#### Abstract

The Friedel-Crafts aroylations of 2- and 4-methylanisole with isophthaloyl dichloride or pyridine-2,6-dicarbonyl dichloride provide respective diones, which on bromination with NBS provide corresponding bisbromomethyl derivatives that undergo simple cyclocondensations with embedded cyclicurea-containing heterocycles, viz. benzimidazol-2(1H)-one, 5-nitrobenzimidazol-2( 1 H )-one, 5,6-dinitrobenzimidazol-2( 1 H )-one, uracil and quinazoline-2,4(1H,3H)-dione to form 11 new bis-oxo-bridged heterocalix[4]arenes (11-19, 24, 25). The X-ray crystal structure of the $\mathbf{1 1}$-benzene complex, ${ }^{1} \mathrm{H}^{-1} \mathrm{H}$ COSY spectra and energy-minimization studies assign partial cone conformations to these heterocalix[4]arenes. The variation in the cyclicurea moiety controls the flexibility of these heterocalix[4]arenes.

The derivatizations on the upper and/or lower rims of conventional calix $[n]$ arenes ${ }^{2}$ and replacement of their phenylene units with heterocyclic moieties ${ }^{3}$ provide tremendous novel opportunities for generating receptors with unique inclusion/ complexation characteristics and related non-covalent hostguest interactions. Whereas extensive work has been done on the modification of hydroxy and para-alkyl groups, ${ }^{2}$ modifications on the methylene bridge(s) in the backbone of calixarenes have been only recently studied. ${ }^{4,5}$ The presence of alkyl and/or aryl group(s) on a methylene carbon creates new stereochemical centres and thus affects the geometries of the resulting calixarenes. ${ }^{4}$ The presence of two bridge(s) in calixarenes could further increase their versatility both due to possible participation of carbonyl group in binding and to their being a chemically reactive and prochiral centre. So far the synthesis of oxo-bridged calixarenes through oxidation of preformed calixarenes has not met with much success. ${ }^{5}$ The cyclizations of preformed oxo-bridged precursors have provided monooxobridged calix[4/5/6]arenes, ${ }^{4 d}$ which exhibit a strong intramolecular H -bonding between carbonyl oxygen and an adjacent phenolic OH group and result in greater conformational flexibility than the parent calixarenes.

In the present investigations, a simple, high yielding, threestep approach, involving Friedel-Crafts aroylation as a key step, has been used to synthesize eleven new heterocalix[4]arenes (11-19, 24, 25) possessing two carbonyl units in place of methylene spacers and one or two heterocyclic units in place of phenylene rings. The ${ }^{1} \mathrm{H}$ NMR, ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY spectra and energy-minimization studies define partial cone conformations to these calixarenes, which has been confirmed in one case, i.e. the 11-benzene complex, by X-ray crystal-structure determination.

## Results and discussion

## Synthesis

Friedel-Crafts aroylation of 2-methylanisole 1a with isophthaloyl dichloride $\mathbf{2 a}$ (2:1) in chloroform in the presence of $\mathrm{AlCl}_{3}$ (anhydrous) provides 3a ( $65 \%$ ), mp $136^{\circ} \mathrm{C}, \mathrm{M}^{+} 374$. The bromination of 3a with N -bromosuccinimide (NBS) provides dibromide $\mathbf{4 a}(80 \%), \mathrm{mp} 120^{\circ} \mathrm{C}, \mathrm{M}^{+} 530$, 532, 534 (1:2:1). The intermolecular cyclocondensation of $\mathbf{4 a}$ with benzimidazol-

2( 1 H )-one 6 under solid-liquid phase-transfer catalytic (PTC) conditions $\left[\mathrm{CH}_{3} \mathrm{CN}-\mathrm{K}_{2} \mathrm{CO}_{3}\right.$-tetrabutylammonium hydrogen sulfate $\left(\mathrm{TBAHSO}_{4}\right)$ ] provides bisoxocalix[1]benzimidazol$2(1 \mathrm{H})$-one[3]arene $11(70 \%), \quad \mathrm{mp} \quad 352-354^{\circ} \mathrm{C}, \quad \mathrm{M}^{+} 504$ (Scheme 1). Similarly, 4a reacts with 5 -nitrobenzimidazol$2(1 H)$-one (7), 5,6-dinitrobenzimidazol-2(1H)-one 8, uracil 9 and quinazoline-2,4( $1 H, 3 H$ )-dione 10 under PTC conditions to provide, respectively, heterocalix[4]arenes 13 ( $35 \%$ ), mp $>355^{\circ} \mathrm{C}, \mathrm{M}^{+} 549 ; 14$ ( $45 \%$ ), $\mathrm{mp}>355^{\circ} \mathrm{C}, \mathrm{M}^{+} 594$; $\mathbf{1 6}$ ( $60 \%$ ), mp 333-335 ${ }^{\circ} \mathrm{C}, \mathrm{M}^{+} 482$ and $\mathbf{1 8}(65 \%), \mathrm{mp} 337-339^{\circ} \mathrm{C}, \mathrm{M}^{+} 532$. Similarly, the reaction of 2-methylanisole 1 a with pyridine-2,6dicarbonyl dichloride 2b provides 3b ( $60 \%$ ), mp $155^{\circ} \mathrm{C}, \mathrm{M}^{+}$ 375. The bromination of $\mathbf{3 b}$ to $\mathbf{4 b}$ and subsequent cyclizations with heterocycles $\mathbf{6 , 9}$ and $\mathbf{1 0}$ provide, respectively, heterocalix[4]arenes $12(45 \%), \mathrm{mp} 299^{\circ} \mathrm{C}, \mathrm{M}^{+} 505$; $17(40 \%)$, mp $335^{\circ} \mathrm{C}$, $\mathrm{M}^{+} 483$ and $19(45 \%), \mathrm{mp} 320^{\circ} \mathrm{C}, \mathrm{M}^{+} 533$. Friedel-Crafts aroylation of $\mathbf{1 b}$ with $\mathbf{2 a}$, subsequent NBS bromination, and cyclization with $\mathbf{8}$ provides heterocalixarene $\mathbf{1 5}$ ( $12 \%$ ), mp $319-320^{\circ} \mathrm{C}, \mathrm{M}^{+}+1791$.
Friedel-Crafts aroylation of 4-methylanisole 20 with isophthaloyl dichloride $\mathbf{2 a}$ (2:1) in chloroform in the presence of $\mathrm{AlCl}_{3}$ (anhydrous) provides 21 ( $17 \%$ ), thick liquid, $\mathrm{M}^{+} 286$ and $22(28 \%), \mathrm{mp} 80^{\circ} \mathrm{C}, \mathrm{M}^{+} 374$. The bromination of 22 with NBS provides dibromide $23(79 \%), \mathrm{mp} 40^{\circ} \mathrm{C}, \mathrm{M}^{+} 530$, 532,534 ( $1: 2: 1$ ). The intermolecular cyclocondensations of $\mathbf{2 3}$ with 6 and 9 provide heterocalix[4]arenes $24(33 \%)$, mp $240^{\circ} \mathrm{C}, \mathrm{M}^{+}$ 504 , and $25(10 \%), \mathrm{mp} 280^{\circ} \mathrm{C} ; \mathrm{M}^{+} 482$ (Scheme 2).

## Conformational analysis

(A) Solid state - X-ray. Compound 11, on recrystallization from chloroform-benzene ( $1: 1 \mathrm{v} / \mathrm{v}$ mixture), forms a 11 -benzene complex of $1: 1$ stoichiometry. The X-ray crystal structure (Fig. 1) of the 11-benzene complex reveals a typical calix inclusion complex, where $\mathbf{1 1}$ attains partial cone conformation with the isophthaloyl unit (ring A) placed in an opposite (anti) direction to the rest of the rings (Fig. 2). The torsion angles ${ }^{6} \varphi$ and $\chi$ around connecting methylene and carbonyl carbons $\mathrm{C}(8)$, $\mathrm{C}(16), \mathrm{C}(23)$ and $\mathrm{C}(31)$ change their signs as,,+-+-++ and -- , indicating a partial cone conformation ${ }^{2 d}$ (Table 1). These four connecting carbons deviate approximately $\pm 0.08 \AA$ from their best fitted mean plane. The interplanar angles between this plane and benzimidazol-2-( 1 H )-one ring (C) and

isophthaloyl ring (A) are $57.7(1)^{\circ}$ and $53.7(1)^{\circ}$ whereas the two methoxy aryl rings B and $\mathrm{B}^{\prime}$ are making dihedral angles $42.8(1)^{\circ}$ and $48.5(1)^{\circ}$, respectively, The dihedral angle between rings $B$ and $B^{\prime}$, and between A and $C$, are $91.3(2)^{\circ}$ and $4.1(1)^{\circ}$, respectively, showing that the two methoxy aryl rings are almost perpendicular whereas the benzimidazol-2-( 1 H )-one
ring ' C ' and isophthaloyl unit ring ' A ' are parallel to each other (Fig. 2). The two rings in pairs A, C and B, B' are placed 7.4(1) $\AA$ and $6.8(1) \AA$ apart, respectively giving rise to an almost square cavity. Both the methoxy groups are anti with respect to the aryl ring B and $\mathrm{B}^{\prime}$ (Table 1) and remain exocyclic to the cavity.

The solvent benzene molecule deviates significantly from planarity, having a maximum rms deviation of $0.09 \AA$ from a least-square plane. This may be due to slight disorder in the ring. The benzene molecule exhibits a face-to-face $\pi-\pi$ interaction with the benzimidazol-2 $(1 \mathrm{H})$-one unit at a distance of 4.08 (1) $\AA$ (Fig. 3). The dihedral angle between the mean plane of these two rings is $19.7(2)^{\circ}$. The benzimidazol- $2(1 \mathrm{H})$-one ring also shows an intermolecular face-to-face $\pi-\pi$ interaction with the isophthaloyl ring of the symmetry-related molecule ( $x$, $y+1, z$ ), at $3.67(1) \mathrm{A}$. Therefore, the benzimidazol-2( 1 H$)$-one ring is sandwiched between a benzene molecule on one side and

an isophthaloyl ring on other side. This gives a stacking of molecules down the ' $b$ ' axis (Fig. 3).

Apart from these $\pi-\pi$ interactions, different molecules are held together by weak $\mathrm{C} \cdots \mathrm{O}$ intermolecular H -bonds (Fig. 3). Imide carbonyl oxygen $\mathrm{O}(1)$ is H -bonded to carbon $\mathrm{C}(15)$ of the methoxy group and aromatic carbon $\mathrm{C}(11)$ of aryl unit B , whereas the oxygens of the bridging carbonyl groups, $\mathrm{O}(3)$ and $\mathrm{O}(4)$, are H -bonded to the bridging methylene carbons $\mathrm{C}(8)$ and $C(31)$, respectively (Table 2 ).
(B) Solution phase - ${ }^{1} \mathbf{H}$ NMR. The rationalization of multiplicities and chemical shifts of various proton signals in the ${ }^{1} \mathrm{H}$ NMR spectra and a comparison with their acyclic counterparts provides a useful tool for assigning the geometries of calixarenes. Assignments of the chemical shifts of various protons have been carried out by decoupling experiments and ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY spectra. For presentation of these data, as far as possible a uniform labelling pattern (Fig. 4) has been adopted. In the case of pyridine-containing calixarenes, as one CH has been replaced by $=\mathrm{N}$-, the $\mathrm{H}^{\mathrm{a}}$ label has been omitted.

The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1 1}$ in $\mathrm{CDCl}_{3}$ shows one singlet due to $2 \times$ OMe protons, one broad singlet at $\delta 5.10$ due to two $\mathrm{NCH}_{2}$ units and signals for ArH . In the aromatic region, irradiation of the triplet ( $\delta .54$ ), which is obviously due to the $\mathrm{H}^{\mathrm{c}}$ proton, converts the multiplet at $\delta 7.75-7.81$ into a distorted singlet. So, the signals of $\mathrm{H}^{\mathrm{b}}$ protons are embedded in this multiplet. Similarly, irradiation of the double doublet at $\delta 8.03$ changes the pattern of the multiplet ( $\delta 7.02-7.13$ ), and thus the signals of $\mathrm{H}^{\mathrm{f}}$ protons are embedded into this multiplet. In the ${ }^{1} \mathrm{H}^{1} \mathrm{H}$ COSY spectrum of $\mathbf{1 1}$, the triplet ( $\mathrm{H}^{c}$ ) shows one cross-peak at $\delta 7.79$ ( $\mathrm{H}^{\mathrm{b}}$, doublet). This doublet ( $\delta 7.79$ ) has one

Table 3 Nature of $\mathrm{NCH}_{2}$ signals and change in the chemical shift of the protons $\mathrm{H}^{\mathrm{a}}$ and $\mathrm{H}^{\mathrm{d}}$ in heterocalixarenes 11-19, 24 and 25 with respect to acyclic precursors

cross-peak at $\delta 7.29\left(\mathrm{H}^{\text {a }}\right.$, singlet). The double doublet ( $\left.\delta 8.03\right)$, which is obviously due to the $\mathrm{H}^{\mathrm{e}}$ proton, has two cross-peaks $\delta 7.75\left(\mathrm{H}^{\mathrm{d}}\right.$, singlet) and $\delta 7.03\left(\mathrm{H}^{\mathrm{f}}\right.$, doublet). The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1 1}$ in $\mathrm{CDCl}_{3}+$ TFA shows an AB quartet (5.03, $5.43, J 17 \mathrm{~Hz}$ ) due to the $\mathrm{NCH}_{2}$ protons.

The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1 2}$ in $\mathrm{CDCl}_{3}$ shows one singlet at $\delta 4.05$ due to OMe protons, one AB quartet at $\delta 4.95,5.27$ due to two $\mathrm{NCH}_{2}$ groups, one singlet at $\delta 6.96$ due to four benzimidazolone aromatic $\mathrm{H}^{\mathrm{s}}$, three doublets at $\delta 7.05,7.41$ and 7.53 due to $\mathrm{H}^{\mathrm{f}}, \mathrm{H}^{\mathrm{d}}$ and $\mathrm{H}^{\mathrm{b}}$, respectively, one triplet at $\delta 7.87$ due to $\mathrm{H}^{\mathrm{c}}$ and one double doublet at $\delta 8.11$ due to $2 \times \mathrm{H}^{\mathrm{e}}$ protons. The well defined ${ }^{1} \mathrm{H}$ NMR spectrum and presence of one AB quartet due to the $\mathrm{NCH}_{2}$ groups point toward a rigid conformation in solution phase. Correlation in various proton signals has been determined by decoupling experiments.

The ${ }^{1} \mathrm{H}$ NMR spectrum of 16 in $\mathrm{CDCl}_{3}+$ TFA exhibits two singlets $(\delta 3.98,4.01)$ for OMe , three broad singlets $(\delta 4.52,5.05$, 5.42) for two $\mathrm{NCH}_{2}$ groups, two doublets $(\delta 7.09,7.13)$ for two aromatic $\mathrm{H}^{\mathrm{f}}$, one multiplet ( $\delta 8.01-8.10$ ) for four aromatic $\mathrm{H}^{\mathrm{e}}$, $\mathrm{H}^{\mathrm{e}^{\prime}}, \mathrm{H}^{\mathrm{b}}$ and $\mathrm{H}^{\mathrm{b}^{\prime}}$, one singlet $(\delta 7.46)$ for $\mathrm{H}^{\mathrm{a}}$, one triplet $(\delta 7.78)$ for $\mathrm{H}^{\mathrm{c}}$, one broad singlet ( $\delta 7.41$ ) for $\mathrm{H}^{\mathrm{d}}$ and $\mathrm{H}^{\mathrm{d}^{\prime}}$, and two doublets $(\delta 6.15,7.59)$ for uracil H . Thus the non-equivalence of $\mathrm{N}-1$ and $\mathrm{N}-3$ positions of the uracil creates a dissymmetry in the calixarene.

In the ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1 8}$, two OMe groups appear as two singlets at $\delta 4.05$ and 4.09 , two $\mathrm{NCH}_{2}$ group constitute two AB quartets, and remaining protons appear in a well defined pattern in the aromatic region. In the ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY spectrum of $\mathbf{1 8}$, two triplets $(\delta 7.40,7.74)$ have cross-peaks against each other. Obviously, these triplets are due to $\mathrm{H}^{\mathrm{h}}$ and $\mathrm{H}^{\mathrm{i}}$. Also, both of these triplets have cross-peaks at $\delta 7.15$ and 8.15. These two peaks are, obviously, due to $\mathrm{H}^{\mathrm{g}}$ and $\mathrm{H}^{\mathrm{j}}$. Because of $\mathrm{H}^{\mathrm{g}}$ being ortho to the carbonyl group, the downfield signal ( $\delta 8.15$ ) could be assigned to $\mathrm{H}^{\mathrm{g}}$. Accordingly, the doublet at $\delta 7.15$ is due to $\mathrm{H}^{\mathrm{j}}$, the triplet at $\delta 7.74$ due to $\mathrm{H}^{\mathrm{h}}$ and the triplet at $\delta 7.40$ due to $\mathrm{H}^{\mathrm{i}}$. Now the triplet at $\delta 7.58\left(\mathrm{H}^{\mathrm{c}}\right)$ has one cross-peak at $\delta 7.85\left(\mathrm{~m}, \mathrm{H}^{\mathrm{b}}\right.$ and $\left.\mathrm{H}^{\mathrm{b}^{\prime}}\right)$ and it has one more cross-peak at $\delta 7.49$ $\left(\mathrm{s}, \mathrm{H}^{\mathrm{a}}\right)$. Similarly, the two multiplets $\delta 7.12-7.22$ and 8.11-8.24 have a correlation and the second multiplet has two cross-peaks at $\delta 6.93$ and 7.01 , which are obviously due to $\mathrm{H}^{\mathrm{d}}$ and $\mathrm{H}^{\mathrm{d}^{\prime}}$. The well defined nature of the spectrum and the appearance of two $\mathrm{NCH}_{2}$ groups as two AB quartets show that the conformation is rigid and the non-equivalence of two cyclic urea nitrogens creates a dissymmetry in the molecule. The heterocalixarenes 17 and 19 show similar patterns in their ${ }^{1} \mathrm{H}$ NMR spectra, which reveal that the conformations are similar.

The change in chemical shifts of $\mathrm{H}^{\mathrm{a}}$ and $\mathrm{H}^{\mathrm{d}}$ in these calixarenes as compared with those H in their precursors is given in Table 3. It may be seen that in all heterocalix[4]arenes 11-19, $\mathbf{2 4}, \mathbf{2 5}, \mathrm{H}^{\mathrm{a}}$ are shifted upfield by the same order $(\Delta \delta-0.7 \pm 0.1)$, which points toward a similar placement of the isophthaloyl

Fig. 5 Energy-minimized partial cone structure of calix[4]arene 11.
unit in these calix[4]arenes. The upfield shift of the protons $\mathrm{H}^{\mathrm{a}}$ $(\Delta \delta-0.7)$ as compared with the acyclic precursors revealed that the isophthaloyl ring is perpendicular to the anisole units and thus $\mathrm{H}^{\mathrm{a}}$ faces the $\pi$-electron ring currents of these adjacent anisole units. Even in 24 and 25 the change in position of the OMe group does not affect their conformations. In the ${ }^{1} \mathrm{H}$ NMR spectra, the $\mathrm{NCH}_{2}$ signals of benzimidazol-2( $1 H$ )one and its nitro derivatives heterocalix[4]arenes (11-15 and 24), appear as singlets (except for 12), but in the case of uracil-based heterocalix[4]arenes (16, 17 and 25), $\mathrm{NCH}_{2}$ appears as two broad singlets or as two AB quartets, and in case of quinazoline-2,4(1H,3H)-dione-based heterocalix[4]arenes ( 18 and 19) $\mathrm{NCH}_{2}$ appears as two AB quartets. Apparently, while moving from benzimidazol- $2(1 \mathrm{H})$-one $\longrightarrow$ uracil $\longrightarrow$ quinazoline-2,4( $1 H, 3 H$ )-dione moieties, the rigidity in conformations of the respective calixarenes increases. As a result, the anisole rings undergo slow rotation (NMR time scale) and $H^{\mathrm{d}}$, which faces the $\pi$-cloud of the opposite ring, is shifted upfield by $\delta 0.5-1.3$. Therefore, these heterocalix[4]arenes possess variable flexibility depending on the nature of the heterocyclic moiety(ies).

MMX energy-minimization studies ${ }^{7}$ on these heterocalix[4]arenes reveal that all of them have by-and-large similar conformations. In these conformations the isophthaloyl ring is placed perpendicular to the adjacent phenylene rings, as shown in their X-ray and ${ }^{1} \mathrm{H}$ NMR spectra. The energy-minimized conformation of the representative case of the heterocalix[4]arenes $\mathbf{1 1}$ is shown in Fig. 5.

Therefore, Friedel-Crafts aroylation of 2- or 4-methylanisole or 2-methylphenyl octyl ether with isophthaloyl dichloride or pyridinedicarbonyl dichloride constitutes a key step of the three-step methodology developed for the synthesis of bis-oxobridged heterocalix[4]arenes. The X-ray crystal structure of the 11-benzene complex, as well as ${ }^{1} \mathrm{H}$ NMR and energyminimization studies, define an inward flattened partial cone conformation to these calixarenes. The flexibility in these heterocalixarenes is affected by the nature of the cyclic urea moiety present.

## Experimental

## General

For general experimental details see ref. 8. In ${ }^{13} \mathrm{C}$ NMR spectral data, the + ve and $-v e$ signals correspond to a DEPT-135 spectrum, and 'ab' corresponds to quaternary carbon signals, which are absent in DEPT-135 but appear in a normal ${ }^{13} \mathrm{C}$ NMR spectrum. 5-Nitrobenzimidazol-2( $1 H$ )-one and 5,6-dinitrobenzimidazol-2 $(1 H)$-one were prepared according to the reported procedures. ${ }^{9}$

## Synthesis of the diones 3a,b, 5a and 22. General procedure

A solution of isophthaloyl dichloride $2 \mathrm{a}(10.0 \mathrm{~g}, 0.05 \mathrm{~mol})$ in chloroform ( 200 ml ) containing suspended $\mathrm{AlCl}_{3}$ (anhyd.)
( $13.5 \mathrm{~g}, 0.11 \mathrm{~mol}$ ) was stirred for 2 h . The solution of 2 methylanisole $\mathbf{1 a}(18.3 \mathrm{~g}, 0.15 \mathrm{~mol}$ ) in chloroform ( 20 ml ) was added dropwise during 30 min . The mixture was stirred for 48 h and then refluxed for 15 min to ensure the completion of the reaction. After cooling in an ice-bath, the reaction mixture was quenched with methanol $(30 \mathrm{ml})$ and washed with water. The organic layer was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ (anhyd.). The chloroform layer was distilled and the residue was crystallized from methanol-dichloromethane mixture to give the pure dione $\mathbf{3 a}$. Similarly, the reaction of the pyridinedicarbonyl dichloride $\mathbf{2 b}$ with 2-methylanisole 1a gave the dione 3b. Similar reactions of 4-methylanisole 20 and 2-methylphenyl octyl ether $\mathbf{1 b}$ with isophthaloyl dichloride provided a mixture of mono ketone 21 and dione 22, and 5a, respectively, which were purified by column chromatography.

## Synthesis of dibromides $\mathbf{4 a}, \mathbf{b}, \mathbf{5 b}$ and 23. General procedure

A solution of dione $3 \mathrm{a}(4.0 \mathrm{~g}, 0.011 \mathrm{~mol})$ in $\mathrm{CCl}_{4}(200 \mathrm{ml})$ containing suspended NBS ( $4.09 \mathrm{~g}, 0.023 \mathrm{~mol}$ ) and benzoyl peroxide ( 50 mg ) was refluxed for 2 h . The solid that separated was filtered off, the filtrate was distilled under vacuum, and the residue was crystallized from methanol to give pure dibromide 4a. Similarly, bromination of diones $\mathbf{3 b}, \mathbf{5 a}$ and $\mathbf{2 2}$ provided the dibromides $\mathbf{4 b}, \mathbf{5 b}$ and 23 .

## Synthesis of heterocalix[4]arenes 11-19, 24, 25. General procedure

A suspension of $\mathbf{4 a}(2.66 \mathrm{~g}, 0.005 \mathrm{~mol})$ in acetonitrile $(800 \mathrm{ml})$ containing benzimidazol- $2(1 \mathrm{H}$ )-one ( $0.67 \mathrm{~g}, 0.005 \mathrm{~mol}), \mathrm{K}_{2} \mathrm{CO}_{3}$ $(10 \mathrm{~g})$ and $\mathrm{TBAHSO}_{4}(50 \mathrm{mg})$ was heated to reflux and progress of reaction was monitored by TLC. After completion of reaction, $\mathrm{K}_{2} \mathrm{CO}_{3}$ was filtered off and washed with acetonitrile. The filtrate and washings were combined, the solvent was distilled off, and the residue was subjected to column chromatography by using ethyl acetate-chloroform ( $20: 80$ ) as eluent to isolate product $\mathbf{1 1}$. Similarly, reactions of $\mathbf{4 a}$ with 5 -nitrobenzimidazol$2(1 H)$-one 7, 5,6-dinitrobenzimidazol-2( 1 H )-one 8, uracil 9 and quinazole-2, $4(1 \mathrm{H}, 3 \mathrm{H})$-dione $\mathbf{1 0}$ provided the respective heterocalix[4]arenes 13, 14, 16 and 18, respectively. The reactions of $\mathbf{4 b}$ with heterocycles $\mathbf{6}, \mathbf{9}$ and $\mathbf{1 0}$ provided heterocalix-
arenes 12, 17 and 19; 5a with $\mathbf{8}$ gave 15; and $\mathbf{2 3}$ with $\mathbf{6}$ and 9 gave 24 and 25 , respectively.

## X-Ray structure analysis of 11-benzene complex $\dagger$

Crystals of 11-benzene were obtained by slow evaporation from chloroform-benzene ( $1: 1 \mathrm{v} / \mathrm{v}$ ) mixture. All intensity-data measurements were carried out at room temperature on a Siemens P4 four-circle diffractometer with graphite-monochromatized $\mathrm{MoK} \alpha$ radiation $(\lambda=0.7169 \AA$ ). The crystals with molecular formula $\mathrm{C}_{37} \mathrm{H}_{30} \mathrm{~N}_{2} \mathrm{O}_{5}$ and relative molecular mass 582.63 belonged to the monoclinic septum, $C 2 / c$ space group with $a=35.636(4), b=9.226(1), c=17.779(2) \AA, V=5839.1(11) \AA^{3}$ $Z=8$. A total of 3885 reflections were collected, out of which 3814 were independent ( $R_{\text {int }}=0.0239$ ) and 2245 were observed [ $I>2 \sigma(I)$ ]. The data were corrected for Lorentz and polarization effects. No absorption correction was applied.
The structure was solved by direct methods using SHELXTL-PC. ${ }^{10} \mathrm{~A}$ full matrix least-squares refinement on $F^{2}$, with anisotropic thermal parameters for all the non-hydrogen atoms, showed disorder in the benzene molecule, as inferred from the short $\mathrm{C}-\mathrm{C}$ distances and high thermal parameters of three carbons [ $\mathrm{C}(35)$ to $\mathrm{C}(37)$ ]. In the initial stages of refinement the benzene molecule $[\mathrm{C}(32)-\mathrm{C}(37)]$ was refined as a rigid group. At final stages of the refinement it was made free but $\mathrm{C}-\mathrm{C}$ distances were fixed at 1.390 (3) $\AA$. No attempt was made to resolve the disordered atoms. All the hydrogens were fixed geometrically and made to ride on their respective atoms.

[^0]The weighting scheme used was

$$
w=\frac{1}{\left[\sigma^{2} F_{\mathrm{o}}^{2}+(0.1414 P)^{2}+4.63 P\right]}
$$

where $P=\left[F_{\mathrm{o}}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right] / 3$
A final refinement ${ }^{11}$ of 397 parameters with six restraints gave $R=0.0717, w R=0.1967$ for observed reflections and $R=0.1286, w R=0.2484$ for all reflections.
