COMPLEX STRUCTURES ON PRODUCT OF CIRCLE BUNDLES OVER COMPLEX MANIFOLDS

PARAMESWARAN SANKARAN AND AJAY SINGH THAKUR

Abstract: Let $\bar{L}_i \longrightarrow X_i$ be a holomorphic line bundle over a compact complex manifold for $i = 1, 2$. Let $S_i$ denote the associated principal circle-bundle with respect to some hermitian inner product on $\bar{L}_i$. We construct complex structures on $S = S_1 \times S_2$ which we refer to as scalar, diagonal, and linear types. While scalar type structures always exist, diagonal type structures are constructed assuming that $\bar{L}_i$ are equivariant $(\mathbb{C}^*)^{n_i}$-bundles satisfying some additional conditions. The linear type complex structures are constructed assuming $X_i$ are (generalized) flag varieties and $\bar{L}_i$ negative ample line bundles over $X_i$. When $H^1(X_1; \mathbb{R}) = 0$ and $c_1(\bar{L}_1) \in H^2(X_1; \mathbb{R})$ is non-zero, the compact manifold $S$ does not admit any symplectic structure and hence it is non-Kähler with respect to any complex structure.

In the case of diagonal type complex structures on $S$, we determine their Picard groups and the field of meromorphic function when $X_i = G_i/P_i$ where $G_i$ are simple and $P_i$ maximal parabolic subgroups.

1. Introduction

H. Hopf [9] gave the first examples of compact complex manifolds which are non-Kähler by showing that $S^1 \times S^{2n-1}$ admits a complex structure for any positive integer $n$. Calabi and Eckmann [5] showed that product of any two odd dimensional spheres admit complex structures. Douady [7], Borcea [3] and Haefliger [8] studied deformations of the Hopf manifolds, and, Loeb and Nicolau [13], following Haefliger’s ideas, studied the deformations of complex structures on Calabi-Eckmann manifolds. More recently, there have been many generalizations of Calabi-Eckmann manifolds leading to new classes of compact complex non-Kähler manifolds by López de Madrano and Verjovsky [14], Meerseman [15], Meersseman and Verjovsky [16], and Bosio [1]. See also [21] and [22].

In this paper we obtain another generalization of the classical Calabi-Eckmann manifolds. Our approach is greatly influenced by the work of Haefliger [8] and of Loeb-Nicolau [13] in that the compact complex manifolds we obtain arise as orbit spaces of a holomorphic $\mathbb{C}$-actions on the product two holomorphic principal $\mathbb{C}^*$-bundles over compact complex manifolds. As a differentiable manifold it is just the product of the associated circle bundles. In fact we obtain a family of complex analytic manifolds which may be thought of as a deformation of the total space of a holomorphic elliptic curve bundle over the product of the compact complex manifolds, in much the same way the construction
of Haefliger (resp. Loeb and Nicolau) yields a deformation of the classical Hopf (resp. Calabi-Eckmann) manifolds.

The basic construction involves the notion of standard action by the torus \((\mathbb{C}^*)^n\) on a principal \(\mathbb{C}^n\)-bundle \(L_1\) over a complex manifold \(X_1\). See Definition 2.1. Let \(L = L_1 \times L_2\) and \(X = X_1 \times X_2\). When \(L_i \rightarrow X_i\) admit standard actions, any choice of a sequence of complex numbers \(\lambda = (\lambda_1, \ldots, \lambda_N)\), \(N = n_1 + n_2\), satisfying the weak hyperbolicity condition of type \((n_1, n_2)\) (in the sense of Loeb-Nicolau [13, p. 788]) leads to a complex structure on the product \(S(L) := S(L_1) \times S(L_2)\) where \(S(L_i)\) denotes the circle bundle over \(X_i\) associated to \(L_i\). This is the diagonal type complex structure on \(S(L)\). The complex structure on \(S(L)\) is obtained by identifying \(S(L)\) as the orbit space of a certain \(\mathbb{C}\)-action determined by \(\lambda\) on \(L\) and by showing that the quotient map \(L \rightarrow L/\mathbb{C}\) is the projection of a holomorphic principal \(\mathbb{C}\)-bundle (Theorem 2.9). The scalar type structure arises as a special case of the diagonal type where \(\mathbb{C}^{n_1} = \mathbb{C}^*\) is the structure group of \(L_i\), \(i = 1, 2\). In the case of scalar type complex structure the differentiable \(S^1 \times S^1\)-bundle with projection \(S(L) \rightarrow X\) is a holomorphic principal bundle with fibre and structure group an elliptic curve.

Under the hypotheses that \(H^1(X_1; \mathbb{R}) = 0\) and \(c_1(L_1) \in H^2(X_1; \mathbb{R})\) is non-zero, we show that \(S(L)\) is not symplectic and is non-Kähler with respect to any complex structure (Theorem 2.13).

The construction of linear type complex structure is carried out under the assumption that \(X_i\) is a generalized flag variety \(G_i/P_i\), \(i = 1, 2\), where \(G_i\) is a simply connected semi simple linear algebraic group over \(\mathbb{C}\) and \(P_i\) a parabolic subgroup and \(L_i\) (i.e., the associated line bundle \(\tilde{L}_i\)) over \(X_i\) is negative ample. In this case \(L_i\) is acted on by the reductive group \(\tilde{G}_i = G_i \times \mathbb{C}^*\) in such a manner that the action of a maximal torus \(\tilde{T}_i \subset \tilde{G}_i\) on \(L_i\) is standard (Proposition 3.1). Fix a Borel subgroup \(\tilde{B}_i \supset \tilde{T}_i\) and choose an element \(\lambda \in \text{Lie}(\tilde{B})\) where \(\tilde{B} = \tilde{B}_1 \times \tilde{B}_2 \subset \tilde{G}_1 \times \tilde{G}_2 =: \tilde{G}\). Writing the Jordan decomposition \(\lambda = \lambda_s + \lambda_u\) where \(\lambda_s\) belongs to the the Lie algebra of \(\tilde{T} := \tilde{T}_1 \times \tilde{T}_2\), we assume that \(\lambda_s\) satisfies the weak hyperbolicity condition. For each such \(\lambda\) we have a complex structure on \(S(L)\) of linear type. (See Theorem 3.2). We show that \(H^q(S_{\lambda}(L); \mathcal{O})\) vanishes for most values of \(q\). This result is valid in greater generality; see Theorem 4.5 for precise statements. We deduce that \(\text{Pic}^0(S_{\lambda}(L)) \cong \mathbb{C}\) (Theorem 4.7). Under the further hypotheses that the \(P_i\) are maximal parabolics and that the complex structure is of diagonal type, we show that the meromorphic function field of \(S_{\lambda}(L)\) is a purely transcendental extension of \(\mathbb{C}\). (Theorem 4.8).

Our proofs in §2, follow mainly the ideas of Loeb and Nicolau [13]. The construction of linear type complex structure is a generalization of the linear type complex structures on \(S^{2m-1} \times S^{2n-1}\) given in [13] to the more general context where the base space is a product of generalized flag varieties. We use the Künneth formula due to A. Cassa [6], besides projective normality and arithmetic Cohen-Macaulayness of generalized flag varieties ([19, 20]), for obtaining our results on the cohomology groups \(H^q(S(L); \mathcal{O})\). Construction of linear type complex structure, applications to Picard groups and the field of meromorphic
functions on $S(L)$ when $X_i = G_i/P_i$ involve some elementary concepts from representation theory of algebraic groups.

**Notations**

The following notations will be used throughout.

- $X_1, X_2$: compact complex manifolds
- $L_1, L_2$: principal $\mathbb{C}^*$-bundles
- $L$: $L_1 \times L_2$
- $\tilde{L}_i$: line bundle associated to $L_i$
- $\tilde{L}^\vee$: dual of $\tilde{L}$
- $\hat{\tilde{L}}_i$: cone over $X_i$ with respect to $\tilde{L}_i^\vee$ when $\tilde{L}_i$ is negative ample
- $T_i, T, \tilde{T}_i, \tilde{T}$: complex algebraic tori $T = T_1 \times T_2$, $\tilde{T}_i = T_i \times \mathbb{C}^*$, $\tilde{T} = \tilde{T}_1 \times \tilde{T}_2$
- $G, G_i$: semi simple complex algebraic groups
- $\hat{G}_i, \hat{G}$: $\hat{G}_i = G_i \times \mathbb{C}^*$, $\hat{G} = G \times \mathbb{C}^*$
- $P_i$: a parabolic subgroup of $G_i$
- $\omega_i, \omega$: dominant integral weights
- $V(\omega_i)$: finite dimensional irreducible $G_i$-module of highest weight $\omega_i$
- $V(\omega_i)\vee$: vector space dual to $V(\omega_i)$
- $V(\omega_1, \omega_2)$: $V(\omega_1) \times V(\omega_2) \setminus (V(\omega_1) \times 0 \cup 0 \times V(\omega_2))$
- $\Lambda(\omega_i), \Lambda(\omega_1, \omega_2)$: weights of $V(\omega_i)$, resp. $V(\omega_1) \times V(\omega_2)$
- $R(G), R$: roots of $G$ with respect to a maximal torus $T$
- $\Phi$: set of simple roots
- $R^+, R_{P_i}$: positive roots, resp. set of positive roots of $G_i$ which are not the roots of Levi part of $P_i$
- $V \hat{\otimes} V'$: completed tensor product of Fréchet-nuclear spaces $V, V'$
- $X_\beta, Y_\beta, H_\beta$: Chevalley basis elements of a reductive Lie algebra
- $\mathcal{O}$: structure sheaf of an analytic space
- $\mathcal{R}^+, \mathcal{R}^-$: \{ $x + \sqrt{-1}y \in \mathbb{C} \mid x > 0$ \}, resp. \{ $x + \sqrt{-1}y \in \mathbb{C} \mid x < 0$ \}
- $I$: unit interval $[0, 1] \subset \mathbb{R}$
- $T_p, M$: tangent space to a manifold $M$ at a point $p$.

**2. Basic construction**

Let $X_1, X_2$ be any two compact complex manifolds and let $p_1 : L_1 \to X_1$ and $p_2 : L_2 \to X_2$ be holomorphic principal $\mathbb{C}^*$-bundles over $X_1$ and $X_2$ respectively. Denote by $p : L_1 \times L_2 =: L \to X := X_1 \times X_2$ the product $\mathbb{C}^* \times \mathbb{C}^*$-bundle. We shall denote by $\tilde{L}_i$ the line bundle associated to $L_i$ and identify $X_i$ with the zero cross-section in $L_i$ so that $L_i = \tilde{L}_i \setminus X_i$. We put a hermitian metric on $L_i$ invariant under the action of $\mathbb{S}^1 \subset \mathbb{C}^*$ and denote by $S(L_i) \subset L_i$ the unit sphere bundle with fibre and structure group $\mathbb{S}^1$. We shall denote by $S(L)$ the $\mathbb{S}^1 \times \mathbb{S}^1$-bundle $S(L_1) \times S(L_2)$. Our aim is to study complex structures on $S(L)$ arising from holomorphic principal $\mathbb{C}$-bundle structures on $L$ with base space $L/\mathbb{C}$. Such a bundle arises from the holomorphic foliation associated to certain holomorphic vector field whose integral curves are biholomorphic to $\mathbb{C}$. For the vector fields we consider, the space of leaves $L/\mathbb{C}$ can be identified with $S(L)$ as a
differentiable manifold and the complex structure on $S(L)$ is induced from that on $L/C$ via this identification.

In this section we consider holomorphic $\mathbb{C}$-actions on $L$ which lead to complex structure on $S(L)$ of scalar and diagonal types. Whereas scalar type complex structures always exist, in order to obtain diagonal type complex structure we need additional hypotheses.

Given any complex number $\tau$ such that $\text{Im}(\tau) > 0$, one obtains a proper holomorphic imbedding $\mathbb{C} \rightarrow \mathbb{C}^* \times \mathbb{C}^*$ defined as $z \mapsto (\exp(2\pi i z), \exp(2\pi i \tau z))$. We shall denote the image by $\mathbb{C}_\tau$. The action of the structure group $\mathbb{C}^* \times \mathbb{C}^*$ on $L$ can be restricted to $\mathbb{C}$ via the above imbedding to obtain a holomorphic principal $\mathbb{C}$-bundle with total space $L$ and base space the quotient space $S_r(L) := L/\mathbb{C}_\tau$. Clearly the projection $L \rightarrow X$ factors through $S_r(L)$ to yield a principal bundle $S_r(L) \rightarrow X$ with fibre and structure group $\mathbb{E} := (\mathbb{C}^* \times \mathbb{C}^*)/\mathbb{C}_\tau$. Since $\mathbb{E}$ is a Riemann surface with fundamental group isomorphic to $\mathbb{Z}^2$, it is an elliptic curve. It can be seen that $\mathbb{E} \cong \mathbb{C}/\Gamma$ where $\Gamma$ is the lattice $\mathbb{Z} + \tau \mathbb{Z} \subset \mathbb{C}$. It is easily seen that $S_r(L)$ is diffeomorphic to $S(L) = S(L_1) \times S(L_2)$. The resulting complex structure on $S(L)$ is referred to as scalar type.

Now suppose that $\tilde{L}_i, X_i$ are acted on holomorphically by the torus group $T_i \cong (\mathbb{C}^*)^{n_i}$ such that $\tilde{L}_i$ is a $T_i$-equivariant bundle over $X_i$. We identify $T_i$ with $(\mathbb{C}^*)^{n_i}$ by choosing an isomorphism $T_i \cong (\mathbb{C}^*)^{n_i}$. Set $N = n_1 + n_2$ and $T := T_1 \times T_2 = (\mathbb{C}^*)^N$. We shall denote by $t_{\lambda,j} : \mathbb{C}^* \rightarrow (\mathbb{C}^*)^N$ the inclusion of the $j$th factor and write $t_{\lambda,j}$ to denote $t_{\lambda,j}(t)$ for $1 \leq j \leq N$. Thus any $t = (t_1, \cdots, t_N) \in T$ equals $\prod_{1 \leq j \leq N} t_{\lambda,j}$, and, under the exponential map $\mathbb{C}^N \rightarrow (\mathbb{C}^*)^N$, $\sum_{1 \leq j \leq N} z_j e_j$ maps to $\prod \exp(z_j) e_j$. (Here $e_j$ denotes the standard basis vector of $\mathbb{C}^N$.)

We put a hermitian metric on $\tilde{L}_i$ which is invariant under action of the maximal compact subgroup $K_i = (S^1)^{n_i} \subset T_i$.

**Definition 2.1.** Let $d$ be a positive integer. We say that the $T_i = (\mathbb{C}^*)^{n_i}$-action on $L_1$ is $d$-standard (or more briefly standard) if the following conditions hold:

(i) the restricted action of the diagonal subgroup $\Delta \subset T_1$ on $L_1$ is via the $d$-fold covering projection $\Delta \rightarrow \mathbb{C}^*$ onto the structure group $\mathbb{C}^*$ of $L_1 \rightarrow X_1$. (Thus if $d = 1$, the action of $\Delta$ coincides with that of the structure group of $L_1$.)

(ii) For any $0 \neq v \in L_1$ and $1 \leq j \leq n_1$ let $\nu_{v,j} : \mathbb{R}_+ \rightarrow \mathbb{R}_+$ be defined as $t \mapsto ||t e_j.v||$. Then $\nu_{v,j}(t) > 0$ for all $t$ unless $\mathbb{R}_+ e_j$ is contained in the isotropy at $v$.

Note that condition (i) in the above definition implies that the $\Delta$-orbit of any $p \in L_1$ is just the fibre of the bundle $L_1 \rightarrow X_1$ containing $p$. The exact value of $d$ will not be of much significance for us. However, it will be too restrictive to assume $d = 1$. See §3.

It is obvious that if $T_i = \mathbb{C}^*$, the structure group of $L_i$, then the action of $T_i$ on $L_i = \tilde{L}_i \setminus X_i$ is standard.

Let $\lambda \in \text{Lie}(T) = \mathbb{C}^N$. There exists a unique Lie group homomorphism $\alpha_\lambda : \mathbb{C} \rightarrow T$ defined as $z \mapsto \exp(z \lambda)$. When $\lambda$ is clear from the context, we write $\alpha$ to mean $\alpha_\lambda$. We denote by $\alpha_{\lambda,i}$ (or more briefly $\alpha_i$) the composition $\mathbb{C} \rightarrow T \xrightarrow{pr} T_i, i = 1, 2$. 
We recall the definition of weak hyperbolicity \[13\]. Let \( \lambda = (\lambda_1, \ldots, \lambda_N) \), \( N = n_1 + n_2 \). One says that \( \lambda \) satisfies the weak hyperbolicity condition of type \((n_1, n_2)\) if
\[
0 \leq \arg(\lambda_i) < \arg(\lambda_j) < \pi, \ 1 \leq i \leq n_1 < j \leq N
\] (1)

If \( \lambda_j = 1 \ \forall j \leq n_1, \lambda_j = \tau \ \forall j > n_1 \), with \( \Im(\tau) > 0 \), we say that \( \lambda \) is scalar type.

We denote by \( C_i \) the cone \( \{ \sum r_j \lambda_j \in \mathbb{C} \mid r_j \geq 0, n_i-1 + 1 \leq j \leq n_i \} \) where \( n_0 = 0 \).

Weak hyperbolicity is equivalent to the requirement that the cones are disjoint and are contained in the half-space \( \{ z \in \mathbb{C} \mid \Im(z) > 0 \} \cup \mathbb{R}_{\geq 0} \). We shall denote \( C_i \setminus \{0\} \) by \( C_i^\circ \) and referred to it as the deleted cone.

**Definition 2.2.** Suppose that the \( T_i = (\mathbb{C}^*)^{n_i} \)-action on \( L_i \) is \( d_i \)-standard for some \( d_i \geq 1 \), \( i = 1,2 \), and let \( \lambda \in \mathbb{C}^N = \text{Lie}(T) \). The analytic homomorphism \( \alpha_\lambda : \mathbb{C} \rightarrow T = (\mathbb{C}^*)^N \) defined as \( \alpha_\lambda(z) = \exp(z\lambda) \) is said to be admissible if \( \lambda \) satisfies the weak hyperbolicity condition (1) of type \((n_1, n_2)\) above. We denote by the image of \( \alpha_\lambda \) by \( C_\lambda \). If \( \alpha_\lambda \) is admissible, we say that the \( C_\lambda\)-action on \( L \) is of diagonal type. If \( \lambda \) is of scalar type, we say that \( C_\lambda\)-action is of scalar type.

The weak hyperbolicity condition implies that \((\lambda_1, \ldots, \lambda_N) \in \mathbb{C}^N \) belongs to the Poincaré domain \[1\], (that is, 0 is not in the convex hull of \( \lambda_1, \ldots, \lambda_N \in \mathbb{C} \)) and that \( \alpha_\lambda \) is a proper holomorphic imbedding. Thus \( C_\lambda \cong \mathbb{C} \). When there is no risk of confusion, we merely write \( \mathbb{C} \) to mean \( C_\lambda \).

**Lemma 2.3.** Suppose that \( L_1 \rightarrow X_1 \) is a \( T_1\)-equivariant principal \( \mathbb{C}^* \)-bundle such that the \( T_1\)-action is \( d \)-standard. Then:

(i) One has \( ||z\epsilon_j.v|| \leq ||v|| \) for \( 0 < |z| < 1 \) where equality holds if and only if \( \mathbb{R}\epsilon_j \) is contained in the isotropy at \( v \).

(ii) For any \( t = (t_1, \ldots, t_{n_1}) \in T_1 \), one has
\[
|t_{k_0}|^d ||v|| \leq ||t.v|| \leq |t_{j_0}|^d ||v||, \forall t \in T_1, \forall v \in L_1, \tag{2}
\]
where \( j_0 \leq n_1 \) (resp. \( k_0 \)) is such that \( |t_{j_0}| \geq |t_j| \) (resp. \( |t_{k_0}| \leq |t_j| \)) for all \( 1 \leq j \leq n_1 \).

Also \( ||t.v|| = |t_{j_0}|^d ||v|| \) if and only if \( |t_j| = |t_{j_0}| \) for all \( j \) such that \( (t_j/t_{j_0}) \epsilon_j.v \neq v \) and \( ||t.v|| = |t_{k_0}|^d ||v|| \) if and only if \( |t_j| = |t_{k_0}| \) for all \( j \) such that \( (t_j/t_{k_0}) \epsilon_j.v \neq v \).

**Proof.** (i) Suppose that \( \mathbb{R}_+ \epsilon_j \) is not contained in the isotropy at \( v \). Since \( K_1 \) preserves the norm, we may assume that \( z \in \mathbb{R}_+ \). In view of [2.1(ii)], \( \nu_{\epsilon_j} \) is strictly increasing. Hence \( ||z\epsilon_j.v|| < ||v|| \) for \( 0 < z < 1 \).

(ii) Write \( s = (s_1, \ldots, s_{n_1}) \) where \( s_j = t_j/t_{j_0} \ \forall j \). Denoting the diagonal imbedding \( \mathbb{C}^* \rightarrow T_1 \) by \( \delta \), we have \( t = \delta(t_{j_0})s \). Now \( \delta(t_{j_0}).v = t_{j_0}^d v \) in view of [2.1(i)].

By repeated application of (i) above, we see that \( ||t.v|| = ||s(\delta(t_{j_0})v)|| = ||s.t_{j_0}^d v|| \leq |t_{j_0}|^d ||v|| \) where the inequality is strict unless \( |t_j| = |t_{j_0}| \) for all \( j \) such that \( s_j \epsilon_j.v \neq v \). A similar proof establishes the inequality \( ||t.v|| \geq |t_{k_0}|^d ||v|| \) as well as the condition for equality to hold. \( \square \)
As an immediate corollary, we obtain

**Proposition 2.4.** Any admissible $\mathbb{C}$-action of diagonal type on $L_1 \times L_2$ is free.

**Proof.** Suppose that $z \in \mathbb{C}, z \neq 0, (p_1, p_2) \in L$. Let $z.(p_1, p_2) = (q_1, q_2)$. It is readily seen that one of the deleted cones $zC_1, zC_2$ lies entirely in the left-half space $\mathcal{R}_- := \{z \in \mathbb{C} \mid \text{Re}(z) < 0\}$ or the right-half space $\mathcal{R}_+ := \{z \in \mathbb{C} \mid \text{Re}(z) > 0\}$. Consider the case $zC_1 \subset \mathcal{R}_-$. Then $|\exp(z\lambda_j)| < 1$ for all $j \leq n_1$. We claim that there is some $j$ such that $\exp(z\lambda_j)\epsilon_j, p_1 \neq p_1$, for otherwise, the action of $T_1$-action, restricted to the orbit through $p_1$ factors through the compact group $T_1/\langle \exp(z\lambda_j)\epsilon_j, 1 \leq j \leq n_1 \rangle \cong (\mathbb{S}^1)^{2n_1}$. This implies that the $T_1$-orbit of $p_1$ is compact, contradicting 2.1 (i). Now it follows from Lemma 2.3 that $\|q_1\| = \|\prod_{1 \leq j \leq n_1} \exp(z\lambda_j)\epsilon_j, p_1\| < \|p_1\|$. Thus $q_1 \neq p_1$ in this case. Similarly, we see that $(p_1, p_2) \neq (q_1, q_2)$ in the other cases also, showing that the $\mathbb{C}$-action on $L$ is free.

**Example 2.5.** (i) Let $T_i = \mathbb{C}^*$ be the structure group of $L_i \rightarrow X_i$ so that the $T_i$-action on $L_i$ is standard, $i = 1, 2$. If $\tau \in \mathbb{C}^*$ is such that $0 < \arg(\tau) < \pi$, then the imbedding $\alpha(z) = (\exp(z), \exp(\tau z)) \in \mathbb{C}^* \times \mathbb{C}^*$ is admissible.

**Lemma 2.6.** The orbits of an admissible $\mathbb{C}$-action on $L$ are closed and properly imbedded in $L$.

**Proof.** Let $p = (p_1, p_2) \in L$. Let $(z_n)$ be any sequence of complex numbers such that $|z_n| \rightarrow \infty$. We shall show that $z_n.p$ has no limit points in $L$. Without loss of generality, we may assume that the $z_n$ are such that $z_n/|z_n|$ have a limit point $z_0 \in \mathbb{S}^1$. By the weak hyperbolicity condition (1), one of the deleted cones $z_0C_i^\circ$ is contained in one of the sectors $S_+(\theta) := \{w \in \mathbb{C} \mid -\theta < \arg(w) < \theta\} \subset \mathcal{R}_+$ or $S_-(\theta) = -S_+(\theta) \subset \mathcal{R}_-$ for some $\theta, -\pi/2 < \theta < \pi/2$. Say $z_0C_i^\circ \subset S_-(\theta)$. Then $z_nC_i^\circ \subset S_-(\theta)$ for all $n$ sufficiently large. It follows that $|\exp(z_n\lambda_j)| \rightarrow 0$ as $n \rightarrow \infty$ for $n_{i-1} < j \leq n_{i-1} + n_i$ (where $n_0 = 0$). By Lemma 2.3 we conclude that the sequence $(\alpha_i(z_n)(p_i))$ does not have a limit in $L_i$.

**Definition 2.7.** Given standard $T_1 = (\mathbb{C}^*)^{n_1}$-actions on the $L_i$, $i = 1, 2$, we obtain holomorphic vector fields $v_1, \ldots, v_N$ on $L = L_1 \times L_2$ as follows. Let $p = (p_1, p_2) \in L$. Suppose that $1 \leq j \leq n_1$. The holomorphic map $\mu_{p_1} : T_1 \rightarrow L_1, s \mapsto s.p_1$, induces $d\mu_{p_1} : \text{Lie}(T_1) = \mathbb{C}^{n_1} \rightarrow T_{p_1}L_1$. Set $v_j(p) := (d\mu_{p_1}(e_j), 0) \in T_{p_1}L_1 \times T_{p_2}L_2 = T_pL$. The vector fields $v_j, n_1 < j \leq N$, are defined similarly.

**Remark 2.8.** Let $1 \leq j \leq n_1$. Consider the differential $dv_1 : T_pL \rightarrow \mathbb{R}$ of the norm map $\nu_1 : L \rightarrow \mathbb{R}_+$ defined as $q = (q_1, q_2) \mapsto ||q_1||$. It is readily verified that, if $\mathbb{R}_+ \epsilon_j$ is not contained in the isotropy at $p_1$, then by standardness of the action, $dv_1(v_j(p)) = v_j(p)(\nu_1) = \nu_j'(p_1) > 0$. (Here $\nu_j, p_1$ is as in the definition 2.1 (ii) of standard action.) On the other hand, since $\nu_1(s.p) = \nu_1(p)$ for all $s \in (\mathbb{S}^1)^{n_1} = \exp(\sqrt{-1}\mathbb{R}^{n_1}) \subset T_1$ we obtain that $dv_1(\sqrt{-1}v_j(p)) = 0$. Thus, for any $z \in \mathbb{C},$ we obtain that $dv_1(zv_j(p)) = \text{Re}(z)v_j'(p_1)$.

An entirely analogous statement holds when $n_1 < j \leq N$. 
Assume that \( \lambda \in \mathbb{C}^N \) yields an admissible imbedding \( \alpha : \mathbb{C} \rightarrow T, \alpha(z) = \exp(z\lambda) \). We obtain a holomorphic vector field \( v_\lambda \) on \( L \) where

\[
v_\lambda(p) = \sum_{1 \leq j \leq N} \lambda_j v_j(p) \in T_pL.
\]

The flow of the vector field \( v_\lambda \) yields a holomorphic action of \( \mathbb{C} \) which is just the restriction of the \( T \)-action to \( \mathbb{C} \lambda \). This \( \mathbb{C} \)-action on \( L \) is free and the \( \mathbb{C} \)-orbits are the same as the leaves of the holomorphic foliation defined by the integral curves of the group projection of a holomorphic principal bundle with fibre and structure group the additive \( S \). The underlying differentiable manifold of the leaf space is diffeomorphic to \( S(L) = S(L_1) \times S(L_2) \). These statements will be proved in Theorem 2.9 below. We shall denote the complex manifold \( L/\mathbb{C} \lambda \) by \( S_\lambda(L) \). The complex structure so obtained on \( S(L) \) is referred to as \textit{diagonal type}.

We shall denote by \( D(\bar{L}) \subset \bar{L} = \bar{L}_1 \times \bar{L}_2 \) the product of the unit disk bundles \( D(\bar{L}_i) = \{ p \in \bar{L}_i | ||p|| \leq 1 \} \subset \bar{L}_i, i = 1, 2 \). Also we denote by \( \Sigma(\bar{L}) \subset \bar{L} \) the boundary of \( D(\bar{L}) \). Thus \( \Sigma(\bar{L}) = D(\bar{L}_1) \times S(L_2) \cup S(L_1) \times D(\bar{L}_2) \). Observe that \( S(L) = D(\bar{L}_1) \times S(L_2) \cap S(L_1) \times D(\bar{L}_2) \subset \Sigma(\bar{L}) \).

\textbf{Theorem 2.9.} With the above notations, suppose that \( \alpha_\lambda : \mathbb{C} \rightarrow T \) defines an admissible action of \( \mathbb{C} \) of diagonal type on \( L \). Then \( L/\mathbb{C} \) is a (Hausdorff) complex analytic manifold and the quotient map \( L \rightarrow L/\mathbb{C} \) is the projection of a holomorphic principal \( \mathbb{C} \)-bundle. Furthermore, each \( \mathbb{C} \)-orbit meets \( S(L) \) transversely at a unique point so that \( L/\mathbb{C} \) is diffeomorphic to \( S(L) \).

Proof of the above theorem, which is along the same lines as the proof of [13, Theorem 1] with suitable modifications to take care the more general setting we are in, will be based on the following two lemmata.

\textbf{Lemma 2.10.} Each \( \mathbb{C} \)-orbit in \( L \) meets \( S(L) \) at exactly one point.

\textit{Proof.} We first show that each orbit meets \( S(L) \) at not more than one point. Let \( p = (p_1, p_2) \in S(L) \). Suppose that \( 0 \neq z \in \mathbb{C} \) is such that \( q := z.p = \alpha(z).p \in S(L) \). This means that, writing \( q = (q_1, q_2) \), we have

\[
q_i = \alpha_i(z)(p_i) = \prod_{n_{i-1} + 1 < j \leq n_{i-1} + n_i} \exp(\lambda_j z) \epsilon_j p_i, \quad i = 1, 2,
\]

(where \( n_0 = 0 \)). Now \( ||q_i|| = ||p_i|| = 1, i = 1, 2, \) and \( p \neq q \). Since the hermitian metric on \( L_1 \) is invariant under \( (\mathbb{S}^1)^{n_1} \), we see that \( ||p_1|| = ||q_1|| = ||(\prod_{1 \leq j \leq n_1} \exp(t_j) \epsilon_j) p_1|| \) where \( t_j = \text{Re}(\lambda_j z) \). Standardness of the \( T_1 \)-action implies that either \( \text{Re}(\lambda_i z) = 0 \) for all \( i \leq n_1 \) or there exist indices \( 1 \leq i_1 < i_2 \leq n_1 \) such that \( \text{Re}(z \lambda_{i_1}).\text{Re}(z \lambda_{i_2}) < 0 \). In the latter case there exists positive reals \( a_1, a_2 \) such that \( a_1 \text{Re}(z \lambda_{i_1}) + a_2 \text{Re}(z \lambda_{i_2}) = 0 \). Similarly, either \( \text{Re}(z \lambda_j) = 0 \) for all \( n_1 < j \leq N \) or there exist indices \( n_1 < j_1 < j_2 \leq N \) and positive reals \( b_1, b_2 \) such that \( b_1 \text{Re}(z \lambda_{j_1}) + b_2 \text{Re}(z \lambda_{j_2}) = 0 \). Suppose \( \text{Re}(a_1 \lambda_{i_1} z + a_2 \lambda_{i_2} z) = 0 \)
Re(b_1\lambda_j z + b_2\lambda_{j2} z). This implies that $a_1\lambda_i + a_2\lambda_{i2} = r(b_1\lambda_j + b_2\lambda_{j2})$ for some positive number $r$. This contradicts the weak hyperbolicity condition (1). Similarly we obtain a contradiction in the remaining cases as well.

Next we show that $\mathbb{C}p \cap \Sigma(\bar{L})$ is path-connected. We shall write $D_-$ and $D_+$ to denote the bounded and unbounded components of $L \setminus \Sigma(\bar{L})$.

Without loss of generality, suppose that $p = (p_1, p_2) \in \Sigma(\bar{L})$ and let $q = (q_1, q_2) \in \Sigma(\bar{L}) \cap \mathbb{C}p$ be arbitrary. Say, $q = z_1, p$ with $z_1 \neq 0$. Then $r \mapsto rz_1, p$ defines a path $\sigma : I \to \mathbb{C}p$ with end points in $\Sigma(\bar{L})$. We modify the path $\sigma$ to obtain a new path which lies in $\Sigma(\bar{L})$. For this purpose choose $z_0 \in \mathbb{C}$, arg$(z_0) > \frac{\pi}{2}$ such that $z_0 C_1^p \cup z_0 C_2^p$ is contained in the left-half space $\mathcal{R}_- = \{z \in \mathbb{C} \mid \text{Re}(z) < 0\}$ and $(-z_0) C_1^p \cup (-z_0) C_2^p$ is contained in the right-half space $\mathcal{R}_+ = \{z \in \mathbb{C} \mid \text{Re}(z) > 0\}$. In particular, $\lim_{r \to \infty} |\exp(-r z_0 \lambda_j)| = \infty$ and $\lim_{r \to \infty} |\exp(r z_0 \lambda_j)| = \infty$, $\forall j \leq N$, where $r$ varies in $\mathbb{R}^+$. By (2), we see that for $i = 1, 2$, and any $x_i \in L_i$, $|\alpha_i(x_0, x_i)| \to 0$ and $|\alpha_i(-x_0, x_i)| \to \infty$ as $r \to +\infty$ in $\mathbb{R}$.

For any $r \in I$, let $\gamma(r) \in \mathbb{R}$ be least (resp. largest) such that $\gamma(r)z_0, \sigma(r) \in \Sigma(\bar{L})$ when $\sigma(r) \in D_+$ (resp. $\sigma(r) \in D_-$). Then $\gamma$ is a well-defined continuous function of $r$. Now $r \mapsto \alpha(\gamma(r)z_0 + rz_1).p$ is a path in $\mathbb{C}p \cap \Sigma(\bar{L})$ joining $p$ to $q$.

To complete the proof, we shall show that there exist points $q' = (q_1', q_2'), q'' = (q_1'', q_2'') \in \mathbb{C}p \cap \Sigma(\bar{L})$ such that $||q_1'|| \leq 1, ||q_2'|| = 1$ and $||q_1''|| = 1, ||q_2''|| \leq 1$. Then any path in $\mathbb{C}p \cap \Sigma(\bar{L})$ joining $q'$ and $q''$ must contain a point of $S(L)$.

Choose $w_k \in \mathbb{C}^*, 1 \leq k \leq 4$, such that the deleted cones $w_1 C_i^p \subset \mathcal{R}_+, w_2 C_i^p \subset \mathcal{R}_-$, for $i = 1, 2$, and, $w_3 C_i^p \subset \mathcal{R}_-, w_4 C_i^p \subset \mathcal{R}_+$. Then $|\exp(rw_k \lambda_j)| \to 0$ (resp. $\infty$) as $r \to +\infty$ ($r \in \mathbb{R}^+$) if $\lambda_j \in C_i^p$ and $w_k C_i^p \subset \mathcal{R}_+$ (resp. $\mathcal{R}_+$). Now $|\alpha_i(rw_k) p_i| < 1, |\alpha_i(rw_k)p_i| > 1, i = 1, 2$ for $r \in \mathbb{R}^+$ sufficiently large. It follows that any path in $\mathbb{C}p$ joining $\alpha(rw_k)(p), k = 1, 2$, must meet $\Sigma(\bar{L})$ for some $r = r_0$. Thus we may as well assume that $p \in \Sigma(\bar{L})$. Suppose that $||p_1|| = 1, ||p_2|| < 1$. For $r > 0$ sufficiently large, $|\alpha_1(rw_3)p_1| < 1$ and $|\alpha_2(rw_3)p_2| > 1$. Therefore there must exist an $r_1$ such that setting $q'_1 = \alpha(r_1w_3)p_i$, we have $||q'_1|| \leq 1$ and $||q'_2|| = 1$. Then $q' = (q'_1, q'_2) \in \mathbb{C}p \cap \Sigma(\bar{L})$ and $q'' := p$ meet our requirements.

If $||p_1|| < 1, ||p_2|| = 1$, we set $q' := p$ and find a $q'' \in \mathbb{C}p \cap \Sigma(\bar{L})$ by the same argument using $w_4$ in the place of $w_3$.\hfill \Box

**Lemma 2.11.** Every $\mathbb{C}_\lambda$-orbit $\mathbb{C}p$, $p \in S(L)$, meets $S(L)$ transversally.

**Proof.** Denote by $\pi : L \to S(L)$ the projection of the principal $(\mathbb{C}^*/\mathbb{S}^1)^2 \cong \mathbb{R}^2_+$-bundle. Evidently, the inclusion $j : S(L) \hookrightarrow L$ is a cross-section and so $L \cong S(L) \times \mathbb{R}^2_+$. The second projection $\nu : L \to \mathbb{R}^2_+$ is just the map $L \ni p = (p_1, p_2) \mapsto (\nu_1(p), \nu_2(p))$ where $\nu_1(p) = ||p_1|| \in \mathbb{R}_+$. One has therefore an isomorphism $T_p L|_{S(L)} \cong T_p S(L) \oplus \mathbb{R}^2$, and the corresponding second projection map $T_p L \to \mathbb{R}^2$ is the differential of $\nu$. Therefore $\mathbb{C}p$ is not transverse to $S(L)$ if and only if $av_\lambda(p) \in T_p S(L)$ for some complex number $a \neq 0$; equivalently, if and only if $dv_i(av_\lambda(p)) = 0, i = 1, 2$, for some $a \neq 0$. 

---

*P. SANKARAN AND A. S. THAKUR*
By Remark 2.8 we have \( dv_\lambda (av_\lambda (p)) = \sum_{1 \leq j \leq n} dv_j (a \lambda_j v_j (p)) = \sum_{1 \leq j \leq n} \text{Re} (a \lambda_j) v_j '(p_1) (1) \). Similarly, \( av_\lambda (p) (v_2) = \sum_{n \leq j \leq N} \text{Re} (a \lambda_j) v_j '(p_2) (1) \). Therefore, \( \mathbb{C} \mathcal{P} \) is not transverse to \( S(L) \) if and only if \( \sum_{1 \leq j \leq N} \text{Re} (a \lambda_j) r_j = 0 = \sum_{n \leq j \leq N} \text{Re} (a \lambda_j) s_j \) for some complex number \( a \neq 0 \) and reals \( r_j, s_k \geq 0 \) (not all zero). This means that \( \sqrt{-1} \mathbb{R} \subset aC_1^0 \cap aC_2^0 \) and hence \( C_1^0 \cap C_2^0 \neq \emptyset \), contradicting the weak hyperbolicity condition.

**Proof of Theorem 2.9:** We shall first show that \( \pi_\lambda : L \rightarrow S(L) \) which sends \( p \in L \) to the unique point in \( \mathbb{C} \mathcal{P} \cap S(L) \) is continuous.

Let \( (p_n) \) be a sequence in \( L \) that converges to a point \( p_0 \in L \). Let \( q_n := \pi_\lambda (p_n) \in S(L) \) and choose \( z_n \in \mathbb{C} \) such that \( z_n, p_n = q_n \). Since \( ||p_n||, ||q_n||, n \geq 1 \), are bounded, it follows by an argument similar to the proof of Lemma 2.10 that \( (z_n) \) is bounded and, passing to a subsequence if necessary, we may assume that it converges to a \( z_0 \in \mathbb{C} \). By the continuity of \( \mathcal{C} \)-action, \( z_m, p_n \rightarrow z_0, p_0 \) as \( m, n \rightarrow \infty \). Therefore \( z_m, p_n = q_n \rightarrow z_0, p_0 \) and \( \pi_\lambda (p_0) = q_0 \) and so \( \pi_\lambda \) is continuous and that the restriction of \( \pi_\lambda \) to \( S(L) \) is a homeomorphism whose inverse is the composition \( S(L) \hookrightarrow L \hookrightarrow L/\mathbb{C} \).

By what has just been shown, \( L/\mathbb{C} \) is in fact a Hausdorff manifold and that \( \pi_\lambda |_{S(L)} \) is a diffeomorphism. The orbit space \( L/\mathbb{C} \) has a natural structure of a complex analytic space with respect to which the projection \( L \rightarrow L/\mathbb{C} \) is analytic. Using Lemma 2.11 we see that \( L \rightarrow L/\mathbb{C} \) is a submersion. It follows that \( L \) is the total space of a complex analytic principal bundle with fibre and structure group \( \mathbb{C} \). The last statement of the theorem follows from Lemmata 2.10 and 2.11.

**Remark 2.12.** (i) When \( X_1 \) is a point, one has \( X \cong X_2, L \cong \mathbb{C}^* \times L_2 \). In this case, the orbit space \( L/\mathbb{C} \) is readily identified with \( L_2/\mathbb{Z} \) where the \( \mathbb{Z} \) action is generated by \( v \mapsto \prod_{2 \leq j \leq N} \exp (2\pi \sqrt{-1} \lambda_j / \lambda_1) \ell_j v \) where \( v \in L_2 \). The projection \( L_2 \rightarrow S_\lambda (L) \) is a covering projection with deck transformation group \( \mathbb{Z} \).

(ii) When \( \lambda \) is of scalar type, the projection \( L \rightarrow X \) factors through \( S_\lambda (L) \) and yields a complex analytic bundle \( S_\lambda (L) \rightarrow X \) with fibre and structure group the elliptic curve \( (\mathbb{C}^* \times \mathbb{C}^*)/\mathbb{C} \). When endowed with diagonal type complex structure the projection \( S_\lambda (L) \rightarrow X \) of the principal \( S^1 \times S^1 \)-bundle, which is smooth, is not complex analytic in general. (Cf. Theorem 4.8)

(iii) When the \( X_i \) do not admit any non-trivial \( T_1 \)-action, we obtain only scalar type complex structures on \( S(L) \). For example, this happens when the \( X_i \) are compact Riemann surfaces of genus at least 2.

We conclude this section with the following observation.

**Theorem 2.13.** Suppose that \( H^1 (X_1; \mathbb{R}) = 0 \) and that \( c_1 (L_1) \in H^2 (X_1; \mathbb{R}) \) is non-zero. Then \( S(L) \) is not symplectic and hence non-Kähler with respect to any complex structure.

**Proof.** In the Leray-Serre spectral sequence over \( \mathbb{R} \) for the \( S^1 \)-bundle with projection \( q : S(L_1) \rightarrow X \) the differential \( d : E^{0,1} \rightarrow H^1 (S^1; \mathbb{R}) \) is non-zero. It follows that \( E^{0,1} = E^{0,1}_\infty = 0 \). Since \( H^1 (X_1; \mathbb{R}) = 0 \), we see that \( H^1 (S(L_1); \mathbb{R}) = 0 \). Hence, by the Künneth formula, \( H^2 (S(L); \mathbb{R}) = H^2 (S(L_1); \mathbb{R}) \oplus H^2 (S(L_2); \mathbb{R}) \).
Let \( u_i \in H^2(S(L_i); \mathbb{R}) \), \( i = 1, 2 \), be arbitrary. Since \( \dim S(L_i) \) is odd for \( i = 1, 2 \), \( u_1^r u_2^s = 0 \) for any \( r, s \geq 0 \) such that \( r + s = n \), where \( 2n := \dim_{\mathbb{R}} S(L) \). Hence \( \omega^n = 0 \) for any \( \omega \in H^2(S(L); \mathbb{R}) \).

3. Complex structures of linear type

Let \( X_i = G_i/P_i, i = 1, 2 \), where the \( G_i \) are simply-connected complex simple linear algebraic groups, \( P_i \) any maximal parabolic subgroup, and \( L_i \) the negative ample generator of the Picard group of \( X_i \). We endow \( \tilde{L}_i \) with a hermitian metric invariant under a suitable maximal compact subgroup \( H_i \subset G_i \). Let \( L = L_1 \times L_2 \) and let \( S(L) \) be product \( S(L_1) \times S(L_2) \) where \( S(L_i) \subset L_i \) is the unit circle bundle over \( X_i, i = 1, 2 \). It can be seen that \( S(L_i) \) is simply-connected. Indeed it is a homogeneous space \( H_i/Q_i \), where \( Q_i \) is connected and is the semi simple part of the centralizer of a circle subgroup contained in \( H_i \) (see [21], [22]). By a classical result of H.-C. Wang [23], it follows that \( S(L) \) admits complex structures invariant under the action of \( H_1 \times H_2 \). The complex structures considered by Wang are the same as those of scalar type considered in §2. The \( H := H_1 \times H_2 \)-action does not preserve the complex analytic structure when \( S(L) \) is endowed with the more general diagonal type complex structures.

In this section we shall construct a complex structure on \( S(L) \) which will be referred to as linear type. Our construction will be more general in that we do not require the parabolics \( P_i \) to be maximal.

Suppose that \( \tilde{L} \longrightarrow G/P \), is a \( G \)-equivariant non-trivial line bundle where \( G \) is simply-connected simple and \( P \) any parabolic. Note that \( G \) acts almost effectively on \( G/P \) and hence on \( L \). (Almost effective means that the subgroup of \( G \) which fixes every element of \( L \) is finite, and since \( G \) simple, is contained in \( Z(G) \), the centre of \( G \).) Let \( T \) be any maximal torus of \( G \). We claim that the \( T \)-action is not \( d \)-standard (with respect to any isomorphism \( T \cong (\mathbb{C}^*)^d \)) for any \( d \geq 1 \). For, if the \( T \)-action were \( d \)-standard, then \( T \) would contain a subgroup \( \Delta \cong \mathbb{C}^* \) whose restricted action is as described in Definition 2.1(i). Since the \( G \)-action commutes with that of the structure group \( \mathbb{C}^* \) of \( \tilde{L} \), it follows that \( z.g(v) = g.z(v) \) for all \( v \in \tilde{L}, z \in \Delta, g \in G \). Since the \( G \)-action on \( L \) is almost effective, we see \( g^{-1}zg = \zeta z \) where \( \zeta \in Z(G) \), the centre of \( G \), which is a finite group. This implies that \( \Delta/Z(G) \) is in the centre of \( G/Z(G) \) contradicting our hypothesis that \( G \) is simple.

Assume that \( \tilde{L} \) is negatively ample, that is, \( \tilde{L}^\vee \) is ample. We shall extend the \( G \)-action on \( \tilde{L} \) to \( \tilde{G} := G \times T_0 \) where \( T_0 \cong \mathbb{C}^* \) acts via a \( d_0 \)-fold covering projection \( T_0 \longrightarrow \mathbb{C}^* \) onto the structure group of \( L \longrightarrow G/P \) for a suitable \( d_0 \). Fix a maximal torus \( T \subset G \). We shall choose \( d_0 \) appropriately so as to obtain a \( d \)-standard action of a maximal torus \( \tilde{T} = T \times \mathbb{C}^* \) of \( \tilde{G} \) where \( d = (l + 1)d_0 \), \( l \) being the rank of \( G \).

We briefly recall some basic facts and notions about the representation theory of \( G \), referring the reader to [10] for details.

Let \( G \) be a semi simple, simply-connected complex linear algebraic group. Let \( T \) be a maximal torus and let \( B \) be a Borel subgroup \( B \) containing \( T \). Let \( l = \dim T \) be the rank
of $G$. Denote by $R(G)$—or more briefly $R$—the set of roots, by $R^+$ the positive roots, by $\Lambda$ the weight lattice and by $Q \subset \Lambda$ the root lattice determined by $T \subset B \subset G$. We shall denote the set of coroots by $R^\vee$. Since $G$ is assumed to be simply connected, $\Lambda = \chi(T)$, the group of characters $T \rightarrow \mathbb{C}^*$ of $T$. Since $B = T.B_u$, $B_u$ being the unipotent, every character of $T$ extends uniquely to a (algebraic) character of $B$ and we have $\chi(T) = \chi(B)$. Let $\Phi^+ \subset R^+$ denote the set of simple positive roots and let $\Lambda^+ \subset \Lambda$ denote the dominant (integral) weights. We shall denote by $W$ the Weyl group of $G$ with respect to $T$. It is generated by the set $S$ of the fundamental reflections $s_\alpha, \alpha \in \Phi^+$. $(W,S)$ is a finite Coxeter group whose longest element will be denoted $w_0$.

For $\omega \in \Lambda^+$, $V(\omega)$ denotes the finite dimensional irreducible highest weight $G$-module with highest weight $\omega$. Also, for any $\omega \in \Lambda$, one has a $G$-equivariant line bundle $L_\omega \rightarrow G/B$ whose total space is $G \times_B \mathbb{C}_{-\omega}$ where $\mathbb{C}_{-\omega}$ is the 1-dimensional $B$-module with character $-\omega : B \rightarrow \mathbb{C}^*$. If $\omega$ is dominant, then $H^0(G/B,L_\omega)^\vee = V(\omega)$ as $G$-module. If $u_\omega \in V(\omega)$ is a highest weight vector, then $P_\omega$, the subgroup of $G$ which stabilizes the 1-dimensional vector space $\mathbb{C} u_\omega$ is a parabolic subgroup that contains $B$ and $L_\omega$ is isomorphic to the pull-back of a line bundle, again denoted $L_\omega$ over $G/P_\omega$. Every parabolic that contains $B$ arises in this manner. Moreover, $L_\omega \rightarrow G/P_\omega$ is (very) ample. If $\omega$ is a positive multiple of a fundamental weight $\varpi$, then $P_\omega$ is a maximal parabolic which corresponds to ‘omitting’ $\varpi$.

Let $\varpi_1, \ldots, \varpi_l$ be the fundamental weights. Consider the homomorphism $\psi : T \rightarrow (\mathbb{C}^*)^l$ of algebraic groups defined as $t \mapsto (\varpi_1(t), \ldots, \varpi_l(t))$. It is an isomorphism since $\varpi_1, \ldots, \varpi_l$ is $\mathbb{Z}$-basis for $\chi(T)$. We shall identify $T$ with $(\mathbb{C}^*)^l$ via $\psi$. Let $\omega \in \Lambda^+$. It is not difficult to see that the $T$-action on $V(\omega) \setminus \{0\} \rightarrow P(V(\omega))$ is not standard since $w_0(\omega) \in \Lambda(\omega)$ is negative dominant, i.e., $-w_0(\omega) \in \Lambda^+$. Write $\mu = \sum_{1 \leq j \leq l} a_{\mu,j} \varpi_j$ for $\mu \in \Lambda(\omega)$ so that $\mu(t) = \prod_{1 \leq j \leq l} t_{\mu,j}$ where $t = (t_1, \ldots, t_l) \in T$. If $v \in V_\mu(\omega)$, then $t.v = \prod_{1 \leq j \leq l} t_{\mu,j}^a v$. Set $d := 1 + \sum |a_{\mu,j}|$ where the sum is over $\mu \in \Lambda(\omega), 1 \leq j \leq l$. The group $T' := T \times \mathbb{C}^*$ acts on $V(\omega)$ where the last factor acts via the covering projection $\mathbb{C}^* \rightarrow \mathbb{C}^*$, $z \mapsto z^{-d}$, where the target $\mathbb{C}^*$ acts as scalar multiplication. Thus $(t,z).v = \mu(t) z^{-d} v$ where $v \in V_\mu(\omega), (t,z) \in T'$. Now consider the $(l+1)$-fold covering projection $\widetilde{T} := (\mathbb{C}^*)^{l+1} \rightarrow T'$, defined as $(t_1, \ldots, t_{l+1}) \mapsto (t_{l+1}^{-1} t_1, \ldots, t_{l+1}^{-1} t_l, \prod_{1 \leq j \leq l+1} t_j^{-1})$. The torus $\widetilde{T}$ acts on the principal $\mathbb{C}^*$-bundle $V(\omega) \setminus \{0\} \rightarrow \mathbb{P}(V(\omega))$ via the above surjection.

Denote by $\widetilde{e}_j : \mathbb{C}^* \rightarrow \widetilde{T}$ the $j$th coordinate imbedding. For any $\mu \in \Lambda(\omega)$, and any $v \in V_\mu(\omega)$, we have $\widetilde{z}_{\mu,j} v = z^d \prod_{1 \leq j \leq l} z^{-a_{\mu,j}} v = z^d \sum a_{\mu,j} v$, and, when $j \leq l$, we have $\widetilde{z}_{\mu,j} v = z^{d+a_{\mu,j}} v$. Also, if $z = (z_0, \ldots, z_0) \in \widetilde{T}$, then $z.v = z_0^{l+1} v = z_0^l v$. Observe that
the exponent of \( z \) that occurs in the above formula for \( z\tilde{e}_j.v \) is positive for \( 1 \leq j \leq l + 1 \) by our choice of \( d' \). We shall denote this exponent by \( d_{\mu,j} \), that is,
\[
d_{\mu,j} = \begin{cases} 
d' + a_{\mu,j}, & 1 \leq j \leq l, \\
d' - \sum_{1 \leq i \leq l} a_{\mu,i}, & j = l + 1, \end{cases}
\]
where \( \mu = \sum_{1 \leq j \leq l} a_{\mu,j} \omega_j \in \Lambda(\omega) \).

Next note that the compact torus \( \tilde{K} := K \times S^1 \subset T \times \mathbb{C}^* \) preserves the hermitian product on \( V(\omega) \) and hence the (induced) hermitian metric on the tautological line bundle over \( \mathbb{P}(V(\omega)) \). From the explicit description of the action just given, it is clear that conditions (i) and (ii) of Definition 2.1 hold. Thus we have extended the \( T \)-action to an action of \( \tilde{T} \)-action which is standard. We are ready to prove

**Proposition 3.1.** We keep the above notations. Let \( \omega \in \Lambda^+ \) be any dominant weight of \( G \). Then the \( T \)-action can be extended to a \( d \)-standard action of \( \tilde{T} := T \times \mathbb{C}^* \) on \( L_{-\omega} \to G/P_\omega \) where \( d = d'(l + 1) \).

**Proof.** Since \( \tilde{L}_\omega \) is a very ample line bundle over \( G/P_\omega \), one has a \( G \)-equivariant embedding \( G/P_\omega \to \mathbb{P}(V(\omega)) \) where \( V(\omega) = H^0(G/P_\omega, L_\omega)^\vee \). By our discussion above, the \( T \)-action on the tautological bundle over the projective space \( \mathbb{P}(V(\omega)) \) has been extended to a \( d \)-standard action of \( \tilde{T} \) for an appropriate \( d > 1 \). The tautological bundle over \( \mathbb{P}(V(\omega)) \) restricts to \( L_{-\omega} \) on \( G/P_\omega \). Clearly the \( L_{-\omega} \) is \( \tilde{T} \)-invariant. Put any \( \tilde{K} \)-invariant hermitian metric on \( V(\omega) \) where \( \tilde{K} \) denotes the maximal compact subgroup of \( \tilde{T} \). As observed above, \( z\tilde{e}_j.v = z^{d_{\mu,j}}v \) where \( d_{\mu,j} > 0 \) for \( v \in V_\mu(\omega) \), it follows that condition (ii) of Definition 2.1 holds. Therefore the \( \tilde{T} \)-action on \( L_{-\omega} \) is \( d \)-standard. \( \square \)

Let \( \pi: \tilde{G} = G \times \mathbb{C}^* \to G \times \mathbb{C}^* \) be the \((l + 1)\)-fold covering obtained from the \((l + 1)\)-fold covering of the last factor and identity on the first. The maximal torus \( \pi^{-1}(T \times \mathbb{C}^*) \) of \( \tilde{G} \) can be identified with \( \tilde{T} \). With respect to an appropriate choice of identification \( \tilde{T} \cong (\mathbb{C}^*)^{l+1} \), we see that the action of \( G \) on \( L_{-\omega} \) extends to \( \tilde{G} \) in such a manner that the \( \tilde{T} \)-action is \( d \)-standard where \( d = (l + 1)d' \) as above. Since \( G/P_\omega = \tilde{G}/\tilde{P} \), where \( \tilde{P} = \pi^{-1}(P_\omega \times \mathbb{C}^*) \), the \( \mathbb{C}^* \)-bundle \( L_{-\omega} \to X \) is \( \tilde{G} \)-equivariant. The parabolic subgroup \( \tilde{P} \) contains the Borel subgroup \( \tilde{B} := \pi^{-1}(B \times \mathbb{C}^*) \). We shall refer to \( \tilde{L}_{-\omega} \to X \) as a \( d \)-standard \( \tilde{G} \)-homogeneous line bundle.

Let \( \tilde{L}_i \to X_i, i = 1, 2 \), be \( d_i \)-standard \( \tilde{G}_i \)-homogeneous line bundles over \( X_i = \tilde{G}_i/\tilde{P}_i \) which are negatively ample. Let \( \tilde{G} = \tilde{G}_1 \times \tilde{G}_2, (\mathbb{C}^*)^N \cong \tilde{T} = \tilde{T}_1 \times \tilde{T}_2 \) where \( N = rank(\tilde{G}) = n_1 + n_2 \) with \( n_i := l_i + 1 \) and \( \tilde{B} = \tilde{B}_1 \times \tilde{B}_2 \).

Let \( \lambda \in Lie(\tilde{B}) \) and let \( \lambda = \lambda_s + \lambda_u \) be its Jordan decomposition, where \( \lambda_s = (\lambda_1, \ldots, \lambda_N) \in \mathbb{C}^N = Lie(\tilde{T}) \) satisfies the weak hyperbolicity condition (1) of type \((n_1, n_2)\) and \( \lambda_u \in Lie(\tilde{B}_u) \), the Lie algebra of the unipotent radical \( \tilde{B}_u \) of \( \tilde{B} \). Thus \([\lambda_u, \lambda_s] = 0 \) in \( Lie(\tilde{B}) \). The analytic imbedding \( \alpha_\lambda : \mathbb{C} \to \tilde{B} \) where \( \alpha_\lambda(z) = \exp(z\lambda) = \exp(z\lambda_s).\exp(z\lambda_u) \) defines an action, again denoted \( \alpha_\lambda \), of \( \mathbb{C} \) on \( L := L_1 \times L_2 \) and an action \( \tilde{\alpha}_\lambda \) on \( V(\omega_1) \times V(\omega_2) \). Denote by \( \mathbb{C}_\lambda \) the image \( \alpha_\lambda(\mathbb{C}) \subset \tilde{B} \). We shall now give
an explicit description of these actions. Let \( v_i \in V(\omega_i) \) and write \( v_i = \sum_{\mu \in \Lambda(\omega_i)} v_\mu \) where \( v_\mu \in V_\mu(\omega_i) \). Set

\[
\lambda_\mu := \sum_{j} \lambda_j d_{\mu,j}
\]

(4)

where the sum ranges over \( n_{i-1} < j \leq n_{i-1} + n_i \) with \( n_0 = 0 \). Then \( \tilde{\alpha}_\lambda(z)(v_1, v_2) = (u_1, u_2) \) where

\[
u_i = \sum_{\mu \in \Lambda(\omega_i)} \prod_j \exp(z \lambda_j) \nu_j \cdot v_\mu = \sum_{\mu} \prod_j \exp(z \lambda_\mu) v_\mu.
\]

(5)

where the product is over \( j \) such that \( n_{i-1} < j \leq n_{i-1} + n_i \).

The \( \mathbb{C} \)-action \( \alpha_\lambda \) on \( L \) is just the restriction to \( L \subseteq V(\omega_1) \times V(\omega_2) \) of the \( \mathbb{C} \)-action \( \tilde{\alpha}_\lambda \).

Since the \( \lambda_\mu \) are all positive linear combination of the \( \lambda_j \), the action of \( \mathbb{C} \) on \( V(\omega_1, \omega_2) := (V(\omega_1) \setminus \{0\}) \times (V(\omega_2) \setminus \{0\}) \), the total space of the product of tautological bundles, is admissible.

Fix a basis for \( V(\omega_i) \) consisting of weight vectors so that \( GL(V(\omega_i)) \) is identified with invertible \( r_i \times r_i \)-matrices, where \( r_i := \dim V(\omega_i) \). Note that action of the diagonal subgroup \( D \) of \( GL(V(\omega_1)) \times GL(V(\omega_2)) \) on \( L(\omega_1, \omega_2) \) is standard and that \( \tilde{T} \) is mapped into \( D \). We put a hermitian metric on \( V(\omega_1) \times V(\omega_2) \) which is invariant under the compact torus \( (\mathbb{S}^1)^{r_1+r_2} \subset D \). Considered as a subgroup of \( GL(V(\omega_1)) \times GL(V(\omega_2)) \), the \( \mathbb{C} \)-action \( \tilde{\alpha}_\lambda \) on \( V(\omega_1, \omega_2) \) is the same as that considered by Loeb-Nicolau corresponding to \( \lambda_\lambda(\omega_1, \omega_2) := (\lambda_\mu, \Lambda(\omega_1), \omega_\nu) \in \text{Lie}(D) = \mathbb{C}^{r_1} \times \mathbb{C}^{r_2} \), where it is understood that each \( \lambda_\mu \) occurs as many times as \( \dim V_\mu(\omega_1) = \mu \in \Lambda(\omega_1) \), and similarly for \( \lambda_\nu, \nu \in \Lambda(\omega_2) \).

**Observation:** The \( \lambda_\lambda(\omega_1, \omega_2) \) satisfy the weak hyperbolicity condition of type \( (r_1, r_2) \) since the \( \lambda_\mu \) are positive integral linear combinations of the \( \lambda_j \).

The differential of the Lie group homomorphism \( \tilde{G}_1 \times \tilde{G}_2 \to GL(V(\omega_1)) \times GL(V(\omega_2)) \)
maps \( \lambda_\lambda \) to the diagonal matrix \( \text{diag}(\lambda_\lambda(\omega_1, \omega_2)) \) and \( \lambda_\mu \) to a nilpotent matrix \( \lambda_\mu(\omega_1, \omega_2) \) which commutes with \( \lambda_\lambda(\omega_1, \omega_2) \). Indeed \( \lambda(\omega_1, \omega_2) := \lambda_\lambda(\omega_1, \omega_2) + \lambda_\mu(\omega_1, \omega_2) \) has a block decomposition compatible with weight-decomposition of \( V(\omega_1) \times V(\omega_2) \), where the \( \mu \)-th block is \( \lambda_\mu I_{m(\mu)} + A_\mu \), where \( A_\mu \) is nilpotent and \( I_{m(\mu)} \) is the identity matrix of size \( m(\mu) \), the multiplicity of \( \mu \in \Lambda(\omega_i), i = 1,2 \).

Recall that, for the \( \mathbb{C} \)-action \( \tilde{\alpha}_\lambda \) on \( V(\omega_1, \omega_2) \), the orbit space \( V(\omega_1, \omega_2)/\mathbb{C} =: S(\omega_1, \omega_2) \) is a complex manifold diffeomorphic to the product of spheres \( \mathbb{S}^{2r_1-1} \times \mathbb{S}^{2r_2-1} \) by \[13\] Theorem \( 1 \). Indeed, the canonical projection \( V(\omega_1, \omega_2) \to S(\omega_1, \omega_2) \) is the projection of a holomorphic principal bundle with fibre and structure group \( \mathbb{C} \).

When \( \lambda_\mu = 0 \), these statements also follows from Theorem \( 2.9 \) above.

**Theorem 3.2.** We keep the above notations.

(i) The orbit space, denoted \( L/\mathbb{C}_\lambda \), of the \( \mathbb{C} \)-action on \( L = L_1 \times L_2 \) defined by \( \lambda = \lambda_\lambda + \lambda_\mu \) is a Hausdorff complex manifold and the canonical projection \( L \to L/\mathbb{C}_\lambda \) is the projection of a principal \( \mathbb{C} \)-bundle. Furthermore, \( L/\mathbb{C}_\lambda \) is analytically isomorphic to \( L/\mathbb{C}_{\lambda_\varepsilon} \) where \( \lambda_\varepsilon := \text{Ad}(t_\varepsilon)(\lambda) \) and \( t_\varepsilon \in \tilde{T} \) is such that \( \gamma(t_\varepsilon) = \varepsilon \) for all \( \gamma \in \Phi^+ \).

(ii) If \( |\varepsilon| \) is sufficiently small, then each orbit of \( \mathbb{C}_{\lambda_\varepsilon} \) on \( L \) meets \( S(L) \) transversally at a
unique point. In particular, the restriction of the projection $L \to L/C_{\lambda}$ to $S(L) \subset L$ is a diffeomorphism.

Proof. When $\lambda_u = 0$, the theorem is a special case of Theorem 2.9. So assume $\lambda_u \neq 0$.

Since the $C$-action $\alpha_{\lambda}$ is conjugate by the analytic automorphism $t_{\varepsilon} : L \to L$ to $\alpha_\lambda$, we see that $L/C_\lambda \cong L/C_{\lambda_\varepsilon}$ as a complex analytic space. Thus, it is enough to prove the theorem for $|\varepsilon| > 0$ sufficiently small.

Consider the projective embedding $\phi_i : X_i = G_i/P_i \hookrightarrow \mathbb{P}(V(\omega_i))$ defined by the ample line bundle $\bar{L}_i$. The circle-bundle $S(L_i) \to X_i$ is just the restriction to $X_i$ of the circle-bundle associated to the tautological bundle over $\mathbb{P}(V(\omega_i))$. Thus $\phi_i$ yields an imbedding $\phi_i : S(L_i) \to S^{2r_1-1}$. Let $\phi : S(L) \to S(V(\omega_1, \omega_2)) = S^{2r_1-1} \times S^{2r_2-1}$ be the product $\phi_1 \times \phi_2$.

Set $\lambda_{\alpha, \varepsilon} = Ad(t_{\varepsilon})\lambda_u$ so that $\lambda_{\varepsilon} = \lambda_s + \lambda_{\alpha, \varepsilon}$. Note that, if $\beta = \sum_{\gamma \in \Phi^+} k_{\beta; \gamma}$ where $\beta \in R^+$, then $Ad(t_{\varepsilon})X_{\beta} = \varepsilon|\beta|X_{\beta}$ where $|\beta| = \sum k_{\beta; \gamma} \geq 1$. (Here $X_{\beta} \in \text{Lie}(B_u)$ denotes a weight vector of weight $\beta$. ) This implies that $\lambda_{\varepsilon} \to \lambda_{\varepsilon}$ as $\varepsilon \to 0$, and, furthermore, $\lambda_{\varepsilon}(\omega_1, \omega_2) \to \lambda_s(\omega_1, \omega_2)$ as $\varepsilon \to 0$. By [13] Theorem 1, for $|\varepsilon|$ sufficiently small, each $C$-orbit for the $\alpha_{\lambda_s}$-action on $S(V(\omega_1, \omega_2))$ is closed and properly imbedded in $L(\omega_1, \omega_2)$ and intersects $S^{2r_1-1} \times S^{2r_2-1}$ at a unique point. In particular, each orbit of the $C$-action corresponding to $\lambda_{\varepsilon}$ meets $S(L) \subset S^{2r_1-1} \times S^{2r_2-1}$ at a unique point when $|\varepsilon| > 0$ is sufficiently small.

Consider the map $\pi_{\lambda_x} : L \to S(L)$ which maps each $\alpha_{\lambda_s}$ orbit to the unique point where it meets $S(L)$. This is just the restriction of $V(\omega_1, \omega_2) \to S^{2r_1-1} \times S^{2r_2-1}$ and hence continuous. It follows that the orbit space $L/C_{\lambda}$ is Hausdorff and that the map $\bar{\pi}_{\lambda_x} : L/C \to S(L)$ induced by $\pi_{\lambda_x}$ is a homeomorphism, whose inverse is just the composition $S(L) \leftarrow L \to L/C$. Since each $C$-orbit for $\alpha_{\lambda_s}$-action meets $S(L)$ transversely by Lemma 2.11, and since $S(L)$ is compact, the same is true for the $\alpha_{\lambda_s}$-action provided $|\varepsilon|$ is sufficiently small. For such an $\varepsilon$, the $\pi_{\lambda_x}$ is a submersion and $\bar{\pi}_{\lambda_x}$ is a diffeomorphism. The orbit space $L/C_{\lambda}$ has a natural structure of a complex analytic space with respect to which $\pi_{\lambda_x}$ is analytic. We have shown above that $L/C_{\lambda}$ is a Hausdorff manifold and that $\pi_{\lambda_x}$ is a submersion. It follows that $\pi_{\lambda_x}$ is the projection of a principal complex analytic bundle with fibre and structure group $C$. 

Definition 3.3. The manifold $S(L)$, with the complex structure induced from $L/C_{\lambda}$ will be said to be of linear type, and will be denoted $S_{\lambda}(L)$.

Remark 3.4. (i) Loeb and Nicolau [13] consider more general $C$-actions on $\mathbb{C}^m \times \mathbb{C}^n$ in which the corresponding vector field is allowed to have higher order resonant terms. In our setup we have only to consider linear actions—the corresponding vector fields can at most have terms corresponding to resonant relations of the form “$\lambda_i = \lambda_j$”.

(ii) When the $P_i$ are maximal parabolics and $L_i$ the negative generators of the Picard group of $G_i/P_i$, the smooth manifold $S(L_i)$ is simply-connected and is a homogeneous
space $H_i/Q_i$ where $H_i \subset G_i$ is simply-connected compact and $Q_i$ is the centralizer of a circle-subgroup contained in $H_i$. Thus $S(L) = S(L_1) \times S(L_2)$ are among the manifolds classified by Wang [23] which admit homogeneous complex structures. The homogeneous complex structures on $S(L)$ correspond to the scalar type. The more general linear type should be thought of as a deformation of the homogeneous complex structure constructed by Wang.

(iii) One has a commuting diagram

$$
L \quad \leftrightarrow \quad V(\omega_1, \omega_2)
$$

$$
\pi_\lambda \downarrow \quad \downarrow \pi_{\lambda(\omega_1, \omega_2)}
$$

$$
S_\lambda(L) \quad \leftrightarrow \quad S^{2r_1-1} \times S^{2r_2-1}
$$

in which the horizontal maps are holomorphic and the vertical maps, projections of holomorphic principal $\mathbb{C}$-bundles.

4. Cohomology of $S_\lambda(L)$

Let $p : L \to X$ be a holomorphic principal $\mathbb{C}^*$-bundle over a compact connected complex manifold. Denote by $\tilde{p} : \tilde{L} \to X$ the associated line bundle (i.e., vector bundle of rank 1). We identify $X$ with the image of the zero cross section in $\tilde{L}$ and $L$ with $\tilde{L} \setminus X$.

We denote the structure sheaf of a complex analytic space $Y$ by $\mathcal{O}_Y$, or more briefly by $\mathcal{O}$ when $Y$ is clear from the context. Recall that a compact subset $A \subset Y$ is called Stein compact if every neighbourhood of $A$ contains a Stein open subset.

Lemma 4.1. Suppose that $f : \tilde{L} \to Y$ is a complex analytic map where $Y$ is a Stein space and is Cohen-Macaulay. Suppose that $f(X) = A \subset Y$ is Stein compact and that $f|_L : L \to Y \setminus A$ is a biholomorphism. Then $H^q(L; \mathcal{O}_L) = 0$ if $0 < q < \dim Y - \dim A - 1$. Furthermore, $H^0(L; \mathcal{O}_L) \cong H^0(Y; \mathcal{O}_Y)$ and the topological vector spaces $H^q(L; \mathcal{O}_L)$ are separated Fréchet-Schwartz spaces for all $q$.

Proof. First note that $H^q(Y; \mathcal{O}_Y) = 0$ unless $q = 0$. By [2] Ch. II, Theorem 3.6, Corollary 3.9], the restriction map $H^q(Y; \mathcal{O}) \to H^q(Y \setminus A; \mathcal{O})$ is an isomorphism for $0 \leq q < \text{depth}_A \mathcal{O}_Y = \dim X - \dim A$ the last equality in view of our hypothesis that $Y$ is Cohen-Macaulay. In view of [2] Ch. I, Theorem 2.19], our hypothesis that $A \subset Y$ is Stein compact implies that $H^i(Y \setminus A; \mathcal{O}) \cong H^i(L, \mathcal{O}_L)$ is separated and Fréchet-Schwartz. As for any open connected complex manifold, $H^{\dim L}(L; \mathcal{O}) = 0$. \hfill \Box

Note that the hypothesis of the above lemma are satisfied in the case when $X$ is a smooth projective variety, $\tilde{L}$ a line bundle such that $L^\vee$ is very ample, and $Y$ is the cone $\tilde{L}$ over $X$ with respect to the projective imbedding determined by $\tilde{L}^\vee$ is Cohen-Macaulay at its vertex $a \in \tilde{L}$. In this case one says that $X$ is arithmetically Cohen-Macaulay. For example, if $X$ is the homogeneous variety $G/P$ where $G$ is a complex linear algebraic group over $\mathbb{C}$ and $P$ a parabolic subgroup and $L$ any negative ample line bundle, then the above properties hold. We will also need the fact that $\tilde{L}$ is normal—that is, $X = G/P$ is projectively normal with respect to any ample line bundle. See [19] for projective normality.
and [20] for arithmetic Cohen-Macaulayness, where these results are established for the more general case of Schubert varieties over arbitrary algebraically closed fields. If we assume that \( L \) itself is very ample, then it is not possible to blow-down \( X \). However, in this case, the following lemma allows one to compute the cohomology groups of \( L \).

**Lemma 4.2.** Let \( L \) be any holomorphic principal \( \mathbb{C}^* \)-bundle over a complex manifold \( X \). Then \( L \cong L^\vee \) as complex manifolds. In particular, \( H^p_q(L) \cong H^p_q(L^\vee) \).

**Proof.** Let \( \psi : L \rightarrow L^\vee \) be the map \( v \mapsto v^\vee \) where \( v^\vee(\lambda v) = \lambda \in \mathbb{C} \). Then \( \psi \) is a biholomorphism. \( \square \)

Suppose that \( L_i \rightarrow X_i, i = 1, 2 \), are projections of holomorphic principal \( \mathbb{C}^* \)-bundles which are negatively ample over complex projective manifolds. We assume that \( X_i \) are arithmetically Cohen-Macaulay. We shall apply the Künneth formula [6] for cohomology with coefficients in coherent analytic sheaves to obtain some vanishing results for the cohomology groups \( H^q(L; \mathcal{O}_L) \).

A coherent analytic sheaf \( \mathcal{F} \) on a complex analytic space \( X \) is a Fréchet sheaf if \( \mathcal{F}(U) \) is a Fréchet space for any open set \( U \subset X \) and if the restriction homomorphism \( \mathcal{F}(U) \rightarrow \mathcal{F}(V) \) is continuous for any open set \( V \subset U \). A Fréchet sheaf \( \mathcal{F} \) is said to be nuclear if \( \mathcal{F}(U) \) is a nuclear space for any open set \( U \subset X \). A Fréchet sheaf \( \mathcal{F} \) is called normal if there exists a basis for \( X \) which is a Leray cover for \( \mathcal{F} \).

If \( X \) is a complex manifold, then any coherent analytic sheaf is Fréchet-nuclear and normal. See [6, p. 927].

Let \( V_1, V_2 \) are Fréchet spaces. We denote by \( V_1 \otimes_{\varepsilon} V_2 \) (resp. \( V_1 \otimes_{\pi} V_2 \)) the inductive (resp. projective) topological tensor product of \( V_1 \) and \( V_2 \). If \( V_1 \) is nuclear, then \( V_1 \otimes_{\pi} V_2 = V_1 \otimes_{\varepsilon} V_2 \). The completed inductive topological tensor product tensor product will be denoted \( V_1 \hat{\otimes} V_2 \). For a detailed exposition on nuclear spaces see [18].

One has the notion of completed tensor product \( \mathcal{F} \hat{\otimes} \mathcal{G} \) of coherent analytic Fréchet nuclear sheaves \( \mathcal{F}, \mathcal{G} \). For example, the structure sheaf of an analytic space is Fréchet nuclear and \( \mathcal{O}_{X \times Y} = \mathrm{pr}_X^* \mathcal{O}_X \hat{\otimes} \mathrm{pr}_Y^* \mathcal{O}_Y \), where \( \mathrm{pr}_X \) denotes the projection \( X \times Y \rightarrow X \).

We apply the Künneth formula for Fréchet-nuclear normal sheaves established by A. Cassa [6, Teorema 3] to obtain the following

**Theorem 4.3.** (i) Suppose that \( L = L_1 \times L_2 \) where \( L_i \rightarrow X_i \) are \( \mathbb{C}^* \)-bundles over connected complex compact manifolds \( X_i \) of dimension \( \dim X_i \geq 1 \). Suppose that, for \( i = 1, 2 \), \( \mathcal{F}_i \) is a coherent analytic sheaf over \( L_i \) such that \( H^q(L_i; \mathcal{F}_i), q \geq 0 \), are Hausdorff. Then

\[
H^q(L; \mathcal{F}_1 \hat{\otimes} \mathcal{F}_2) \cong \sum_{k+l=q} H^k(L_1; \mathcal{F}_1) \hat{\otimes} H^l(L_2; \mathcal{F}_2)
\]  

for \( q \geq 0 \).

(ii) Assume that \( X_i \) are projective manifolds and \( L_i^p \) are very ample line bundles such that the \( \hat{L}_i \) are Cohen-Macaulay. Then \( H^q(L; \mathcal{O}_L) = 0 \) except possibly when \( q = 0, \dim X_1, \dim X_2, \dim X_1 + \dim X_2 \). Also, \( H^0(L; \mathcal{O}_L) \cong H^0(L_1; \mathcal{O}_{L_1}) \hat{\otimes} H^0(L_2; \mathcal{O}_{L_2}) \)
Proof. (i) The isomorphism (6) follows from the Künneth formula [6, Theorem 3].

(ii) Let \( a_i \) denote the vertex of the cone \( \hat{L}_i \) over \( X_i \) with respect to the projective imbedding determined by \( L_i \). Then \( \hat{L}_i \) is an affine variety and hence Stein. By [2, Corollary 2.21, Chapter I] the cohomology groups \( H^q(L_i; \mathcal{O}_{L_i}) = H^q(\hat{L}_i \setminus \{a_i\}; \mathcal{O}_{L_i}), q \geq 0 \), are separated and Fréchet-Schwartz. Since, by hypothesis \( \hat{L}_i \) is Cohen-Macaulay at \( a_i \), we have \( H^q(L_i; \mathcal{O}_{L_i}) \cong H^q(\hat{L}_i; \mathcal{O}_{L_i}) = 0 \) if \( 0 < q < \dim X_i \) by [2, Theorem 3.6, Chapter II]. The rest of the theorem now follows readily from (6).

Remark 4.4. (i) We remark that the vanishing of the cohomology groups \( H^q(L; \mathcal{O}_L) \) for \( 0 < q < \min\{\dim X_1, \dim X_2\} \) in Theorem [1,3] (ii) follows from [2, Ch. I, Theorem 3.6]. To see this, set \( \hat{L} := \hat{L}_1 \times \hat{L}_2 \setminus A \), where \( A \) is the closed analytic space \( A = \hat{L}_1 \times \{a_2\} \cup \{a_1\} \setminus \hat{L}_2 \). The ideal \( \mathcal{I} \subset \mathcal{O}_L \) of \( A \) equals \( \mathcal{I}_1 \mathcal{I}_2 \) where \( \mathcal{I}_1, \mathcal{I}_2 \) are the ideals of the components \( A_1 := \hat{L}_1 \times \{a_2\}, A_2 := \{a_1\} \setminus \hat{L}_2 \) of \( A \). Then \( \text{depth}_A \mathcal{O}_L = \text{depth}_{\mathcal{I}_1} \mathcal{O}_L = \min_j\{\text{depth}_{\mathcal{I}_j} \mathcal{O}_{L_j}\} = \min\{\dim X_1 + 1, \dim X_2 + 1\} \). Thus we see that \( \text{depth}_A \mathcal{O}_L = \min\{\dim X_1 + 1, \dim X_2 + 1\} \). Therefore \( H^q(\hat{L}_1 \times \hat{L}_2; \mathcal{O}_{\hat{L}_1 \times \hat{L}_2}) \cong H^q(L; \mathcal{O}_L) \) if \( q < \min\{\dim X_1, \dim X_2\} \) by [2, Ch. I, Theorem 3.6] where the isomorphism is induced by the inclusion. Since \( \hat{L}_1 \times \hat{L}_2 \) is Stein, the cohomology groups \( H^q(L; \mathcal{O}_L) \) vanish for \( 1 \leq q < \min\{\dim X_1, \dim X_2\} \).

(ii) When \( \pi_1 : L_1 \longrightarrow X_1 \) is an algebraic \( \C^* \)-bundle over a smooth projective variety \( X_1 \), one has an isomorphism of quasi-coherent algebraic sheaves \( \pi_{1,*}(\mathcal{O}_{L_1}^{\text{alg}}) \cong \oplus_{k \in \mathbb{Z}} L_k^k \mathcal{O}_{\pi_1^{-1}(L_k)} \) of \( \mathcal{O}_X \)-modules. (By the GAGA principle, \( H^*_\text{alg}(X_1; \mathcal{L}_1^k) \cong H^*(X_1; \mathcal{L}_1^k) \) for all \( k \in \mathbb{Z} \)). Therefore the algebraic cohomology groups \( H^q_{\text{alg}}(L_1; \mathcal{O}_{L_1}^{\text{alg}}) \) can be calculated as \( H^q_{\text{alg}}(L_1; \mathcal{O}_{L_1}^{\text{alg}}) \cong H^q(X_1; \mathcal{O}_{\pi_1^{-1}(L_k)}) \). If \( X_1 \) is a flag variety and \( \pi_1 \), negative ample, then it is known that \( H^q(X_1; \mathcal{L}_1^k) = 0 \) except when \( k > 0 \) (resp. \( k \leq 0 \)) and \( q = \dim X_1 \) (resp. \( q = 0 \)). Furthermore, \( H^0(X_1; \mathcal{L}_1^k) \cong H^{\dim X_1}(X_1; \mathcal{L}_1^{-k})^\vee \) for \( k < 0 \). Hence \( H^q_{\text{alg}}(L_1; \mathcal{O}_{L_1}^{\text{alg}}) = 0 \) unless \( q = 0 \) or \( q = \dim X_1 \). Now \( H^q_{\text{alg}}(L_1; \mathcal{O}_{L_1}^{\text{alg}}) \cong \oplus_{k > 0} H^{\dim X_1}(X_1; \mathcal{L}_1^k) \) and \( H^0_{\text{alg}}(L_1; \mathcal{O}_{L_1}^{\text{alg}}) \cong \oplus_{k \leq 0}(X_1; \mathcal{L}_1^k) \). We do not know the relation between \( H^{\dim X_1}(L_1; \mathcal{O}) \) and \( H^q_{\text{alg}}(L_1; \mathcal{O}_{L_1}^{\text{alg}}) \).

Suppose that \( \alpha_\lambda \) is an admissible \( \mathbb{C} \)-action on \( L \longrightarrow X \) of scalar type, or diagonal type, or linear type. It is understood that in the case of diagonal type, there is a standard \( T_1 \)-action on \( X_i, i = 1, 2 \), and that \( X_i = G_i / P_i \) and \( L_i \) negative ample in the case of linear type action. Denote by \( \psi \) (or more briefly \( \psi \)) the holomorphic vector field on \( L \) associated to the \( \mathbb{C} \)-action. Thus the \( \mathbb{C} \)-action is just the flow associated to \( \psi \). We shall denote by \( \mathcal{O}_v^{\text{tr}} \) the sheaf of germs of local holomorphic functions which are constant along the \( \mathbb{C} \)-orbits. Thus \( \mathcal{O}_v^{\text{tr}} \) is isomorphic to \( \pi_{\lambda,*}(\mathcal{O}_{S_\lambda(L)}) \). One has an exact sequence of sheaves \( 0 \longrightarrow \mathcal{O}_v^{\text{tr}} \longrightarrow \mathcal{O}_L \xrightarrow{v} \mathcal{O}_L \longrightarrow 0 \). (7)

Since the fibre of \( \pi_\lambda : L \longrightarrow S_\lambda(L) \) is Stein, we see that \( H^q(L; \mathcal{O}_v^{\text{tr}}) \cong H^q(S_\lambda(L); \mathcal{O}_{S_\lambda(L)}) \) for all \( q \). Thus, the exact sequence (7) leads to the following long exact sequence:

\[
0 \longrightarrow H^0(S_\lambda(L); \mathcal{O}_{S_\lambda(L)}) \longrightarrow H^0(L; \mathcal{O}_L) \longrightarrow H^0(L; \mathcal{O}_L) \longrightarrow H^1(S_\lambda(L); \mathcal{O}_{S_\lambda(L)}) \longrightarrow \cdots
\]
\[ H^q(S_\lambda(L); \mathcal{O}_{S_\lambda(L)}) \to H^q(L; \mathcal{O}_L) \to H^q(L; \mathcal{O}_L) \to H^{q+1}(S_\lambda(L); \mathcal{O}_{S_\lambda(L)}) \to \cdots \] \hspace{1cm} (8)

**Theorem 4.5.** Suppose that \( L = L_1 \times L_2 \) where the \( L_i \) satisfy the hypotheses of Theorem 4.3. Suppose that \( 1 \leq \dim X_1 \leq \dim X_2 \). Then \( H^q(S_\lambda(L); \mathcal{O}) = 0 \) provided \( q \notin \{0, 1, \dim X_1, \dim X_1 + 1, \dim X_1 + \dim X_2, \dim X_1 + \dim X_2 + 1; i = 1, 2\} \). Moreover one has \( \mathbb{C} \subset H^1(S_\lambda(L); \mathcal{O}) \), given by the constant functions in \( H^0(L; \mathcal{O}) \).

**Proof.** The only assertion which remains to be explained is that the constant function 1 is not in the image of \( v_* : H^0(L; \mathcal{O}) \to H^0(L; \mathcal{O}) \). All other assertions follow trivially from the long exact sequence (8) above and Theorem 4.3.

Suppose that \( f : L \to \mathbb{C} \) is such that \( v(f) = 1 \). This means that \( \frac{d}{dz} \big|_{z=0} (f \circ \mu_p)(z) = 1 \) for all \( p \in L, z \in \mathbb{C} \), where \( \mu_p : \mathbb{C} \to L \) is the map \( z \mapsto \alpha_\lambda(z), p = z.p \). Since \( \mu_\lambda \mu_p(z) = z.(w.p) = (z + w).p = \mu_p(z + w) \), it follows that \( \frac{d}{dz} \big|_{z=w} (f \circ \mu_p) = 1 \) \( \forall w \in \mathbb{C} \). Hence \( f \circ \mu_p(z) = z + f(p) \). This means that the complex hypersurface \( Z(f) := f^{-1}(0) \subset L \) meets each fibre at exactly one point. It follows that the projection \( L \to S_\lambda(L) \) restricts to a bijection \( Z(f) \to S_\lambda(L) \).

In fact, since \( v(f) \neq 0 \) we see that \( Z(f) \) is smooth and since \( v_p \) is tangent to the fibres of the projection \( L \to S_\lambda(L) \) for all \( p \in Z(f) \), we see that the bijective morphism of complex analytic manifolds \( Z(f) \to S_\lambda(L) \) is an immersion. It follows that \( Z(f) \to S_\lambda(L) \) is a biholomorphism. Thus \( Z(f) \) is a compact complex analytic sub manifold of \( L \subset \tilde{L} \). Since \( \tilde{L} \) is Stein, this is a contradiction. \( \square \)

Our next result concerns the Picard group of \( S_\lambda(L) \).

**Proposition 4.6.** Let \( L_i \to X_i \) be as in Theorem 4.3 (ii). Suppose that \( X_i \) is simply connected. Then \( \text{Pic}^0(S_\lambda(L_i)) \cong \mathbb{C}^1 \) for some \( l \geq 1 \).

**Proof.** Since \( \tilde{L} \) is negative ample, \( c_1(L_i) \in H^2(X_i; \mathbb{Z}) \) is a non-torsion element. Clearly \( H^1(S_\lambda(L); \mathbb{Z}) = 0 \) by a straightforward argument involving the Serre spectral sequence associated to the principal \( S^1 \times S^1 \)-bundle with projection \( S(L) \to X_1 \times X_2 \). Using the exact sequence \( 0 \to \mathbb{Z} \to \mathcal{O} \to \mathcal{O}^* \to 1 \) we see that \( \text{Pic}^0(S_\lambda(L)) \cong H^1(S_\lambda(L); \mathcal{O}) \cong \mathbb{C}^l \).

Now \( l \geq 1 \) by Theorem 4.3. \( \square \)

The above proposition is applicable when \( X_i = G_i/P_i \) and \( \bar{L}_i \) are negative ample. However, in this case we have the following stronger result.

**Theorem 4.7.** Let \( X_i = G_i/P_i \) where \( P_i \) is any parabolic subgroup and let \( \bar{L}_i \to X_i \) be a negative line bundle, \( i = 1, 2 \). We assume that, when \( X_i = \mathbb{P}^1 \), the bundle \( L_i \) is a generator of \( \text{Pic}(X_i) \). Then \( \text{Pic}^0(S_\lambda(L_i)) \cong \mathbb{C} \). If the \( P_i \) are maximal parabolics and the \( L_i \) are generators of \( \text{Pic}(X_i) \cong \mathbb{Z} \), then \( \text{Pic}(S_\lambda(L)) \cong \text{Pic}^0(S_\lambda(L)) \cong \mathbb{C} \).

**Proof.** It is easy to see that \( H^1(S(L); \mathbb{Z}) = 0 \) and that, when \( P_i \) are maximal parabolics and \( L_i \) generators of \( \text{Pic}(X_i) \cong \mathbb{Z} \), \( S(L) \) is 2-connected. If \( \dim X_i > 1 \) for \( i = 1, 2 \), then \( H^1(L; \mathcal{O}) = 0 \) by Theorem 4.3 and so we need only show that \( \text{coker}(H^0(L; \mathcal{O}) \overset{v}{\to} H^0(L; \mathcal{O})) \) is isomorphic to \( \mathbb{C} \). In case \( \dim X_i = 1 \)—equivalently \( X_i = \mathbb{P}^1 \)—\( \bar{L}_i \) is the
tautological bundle by our hypothesis. Thus \( L_i = \mathbb{C}^2 \setminus \{0\} \). In this case we need to also show that \( \ker(H^1(L; \mathcal{O}) \to H^1(L; \mathcal{O})) \) is zero. Note that the theorem is known due to Loeb and Nicolau [13, Theorem 2] when both the \( X_i \) are projective spaces and the \( L_i \) are negative ample generators—in particular when both \( X_i = \mathbb{P}^1 \).

The validity of the theorem for the case when \( \lambda \) is of diagonal type implies its validity in the linear case as well. This is because one has a family \( \{L/\mathbb{C}_{\lambda_i}\} \) of complex manifolds parametrized by \( \epsilon \in \mathbb{C} \) defined by \( \lambda_i = \lambda_s + \lambda_{u,\epsilon} \), where \( S_{\lambda}(L) = L/\mathbb{C}_{\lambda} \cong L/\mathbb{C}_\lambda \) if \( \epsilon \neq 0 \) and \( \lambda_0 := \lambda_s \) is of diagonal type. (See §3.) The semi-continuity property ([11] Theorem 6, §4] for \( \dim H^1(S_{\lambda}(L); \mathcal{O}) \) implies that \( \dim H^1(S_{\lambda}(L); \mathcal{O}) \leq \dim H^1(S_{\lambda_s}(L); \mathcal{O}) \). But Theorem [13] says that \( \dim H^1(S_{\lambda}(L); \mathcal{O}) \geq 1 \) and so equality must hold, if \( H^1(S_{\lambda_s}(L); \mathcal{O}) \cong \mathbb{C} \). Therefore we may (and do) assume that the complex structure is of diagonal type.

First we show that \( \text{coker}(v_s : H^0(L; \mathcal{O}) \to H^0(L; \mathcal{O})) \) is 1-dimensional, generated by the constant functions. Consider the commuting diagram where \( \tilde{v} \) is the holomorphic vector field defined by the action of \( \mathbb{C} \) given by \( \lambda(\omega_1, \omega_2) \) on \( V(\omega_1, \omega_2) \). Note that \( v_x = \tilde{v}_x \) if \( x \in L \).

\[
\begin{array}{ccc}
H^0(V(\omega_1, \omega_2); \mathcal{O}) & \xrightarrow{\tilde{v}_s} & H^0(V(\omega_1, \omega_2); \mathcal{O}) \\
\downarrow & \ & \downarrow \\
H^0(L; \mathcal{O}) & \xrightarrow{v_s} & H^0(L; \mathcal{O})
\end{array}
\]

By Hartog’s theorem, \( H^0(V(\omega_1, \omega_2); \mathcal{O}) \cong H^0(V(\omega_1) \times V(\omega_2); \mathcal{O}) \). Also, since \( \hat{L}_i \) is normal at its vertex [19], again by Hartog’s theorem, \( H^0(L; \mathcal{O}) \cong H^0(\hat{L}_1 \times \hat{L}_2; \mathcal{O}) \). Since \( \hat{L}_i \subset V(\omega_i) \) are closed sub varieties, it follows that the both vertical arrows, which are induced by the inclusion of \( L \) in \( V(\omega_1, \omega_2) \), are surjective. \( \hat{f} \)From what has been shown in the proof of Theorem [13] we know that the constant functions are not in the cokernel of \( v_s \).

So it suffices to show that \( \text{coker}(\tilde{v}_s) \) is 1-dimensional. This was established in the course of proof of Theorem 2 of [13]. For the sake of completeness we sketch the proof. We identify \( V(\omega_i) \) with \( \mathbb{C}^{r_i} \), where \( r_i := \dim V(\omega_i) \), by choosing a basis for \( V(\omega_i) \) consisting of weight vectors. Let \( r = r_1 + r_2 \) so that \( \mathbb{C}^r \cong V(\omega_1) \times V(\omega_2) \). The problem is reduced to the following: Given a holomorphic function \( f : \mathbb{C}^r \to \mathbb{C} \) with \( f(0) = 0 \), solve for a holomorphic function \( \phi \) satisfying the equation

\[
\sum_{i \leq j} b_{ij} z_j \frac{\partial \phi}{\partial z_j} = f, \quad (9)
\]

where we may (and do) assume that \( \phi(0) = 0 \). In view of the \textit{Observation} made preceding the statement of Theorem [32] we need only to consider the case where \( (b_{ij}) \in \mathbb{C}^r \) satisfies the weak hyperbolicity condition of type \( (r_1, r_2) \). Denote by \( z^m \) the monomial \( z_1^{m_1} \ldots z_r^{m_r} \) where \( m = (m_1, \ldots, m_r) \) and by \( |m| \) its degree \( \sum_{1 \leq j \leq r} m_j \). Let \( f(z) = \sum_{|m| > 0} a_{m} z^m \in H^0(\mathbb{C}^r; \mathcal{O}) \). Then \( \phi(z) = \sum a_{m} / (b_{m}) z^m \) where \( b_{m} = \sum b_{ij} m_j \) is the unique solution of Equation (9). Note that weak hyperbolicity and the fact that \( |m| > 0 \) imply that \( b_{m} \neq 0 \), and, \( b_{m} \to \infty \) as \( m \to \infty \). Therefore \( \phi \) is a convergent power series and so \( \phi \in H^0(\mathbb{C}^r; \mathcal{O}) \).
It remains to show that, when $X_1 = \mathbb{P}^1$, $L_1 = \mathbb{C}^2 \setminus \{0\}$, and dim $X_2 > 1$, the homomorphism $v_* : H^1(L; O) \to H^1(L; O)$ is injective. Let $z_j, 1 \leq j \leq r$, denote the coordinates of $\mathbb{C}^2 \times V(\omega_2)$ with respect to a basis consisting of $T$-weight vectors. Since dim $X_2 > 1$, we have $H^1(L_2; O) = 0$. Also $H^1(L_1; O) = H^1(\mathbb{C}^2 \setminus \{0\}; O)$ is the space $A$ of convergent power series $\sum_{m_1, m_2 < 0} a_{m_1, m_2} z_1^{m_1} z_2^{m_2}$ in $z_1^{-1}, z_2^{-1}$ without constant terms.

By Theorem 1.3, $H^1(L; O) = A \hat{\otimes} H^0(\hat{L}_2; O) \cong A \hat{\otimes} H^0(\hat{L}_2; O)$. Let $I \subset H^0(V(\omega_2); O)$ denote the ideal of functions vanishing on $\hat{L}_2$ so that $H^0(\hat{L}_2; O) = H^0(V(\omega_2); O) / I$. One has the commuting diagram

$$
0 \to A \hat{\otimes} I \to A \hat{\otimes} H^0(V(\omega_2); O) \to A \hat{\otimes} H^0(\hat{L}_2; O) \to 0
$$

$$
0 \to A \hat{\otimes} I \to A \hat{\otimes} H^0(V(\omega_2); O) \to A \hat{\otimes} H^0(\hat{L}_2; O) \to 0
$$

where the rows are exact. Theorem 2 of [13] implies that $\tilde{v}_* : A \hat{\otimes} H^0(V(\omega_2); O) \to A \hat{\otimes} H^0(V(\omega_2); O)$ is an isomorphism. As before, this is equivalent to showing that Equation (9) has a (unique) solution $\phi$ without constant term when $f = \sum m c_m z^m \in A \hat{\otimes} H^0(V(\omega_2); O)$, is any convergent power series in $z_1^{-1}, z_2^{-1}, z_j, 3 \leq j \leq r$, where the sum ranges over $m = (m_1, m_2, \ldots, n_r) \in \mathbb{Z}^r, m_1, m_2 < 0, m_j > 0, \forall j \geq 3$. It is clear that $\phi(z) = \sum c_m / b(m) z^m$ is the unique formal solution. Note that weak hyperbolicity condition implies that $b \cdot m \neq 0$ and $b \cdot m \to \infty$ as $\sum_{j \geq 1} |m_j| \to \infty$. So $\phi(z)$ is a well-defined convergent power series in the variables $z_1^{-1}, z_2^{-1}, z_j, j \geq 3$ and is divisible by $z_1^{-1} z_2^{-1}$. Hence $\phi \in A \hat{\otimes} H^0(L_2; O)$ and so $\tilde{v}_* : A \hat{\otimes} H^0(L_2; O) \to A \hat{\otimes} H^0(L_2; O)$ is an isomorphism. The ideal $I$ is stable under the action of $\hat{T}_2$, and so is generated as an ideal by (finitely many) polynomials in $z_3, \ldots, z_n$ which are $\hat{T}_2$-weight vectors. In particular, the generators are certain homogeneous polynomials $h(z_3, \ldots, z_n)$ such that $\tilde{v}_*(z_1^{m_1} z_2^{m_2} h) = b \cdot m z_1^{m_1} z_2^{m_2} h \forall m_1, m_2 \in \mathbb{Z}$ where $z^m$ is any monomial that occurs in $z_1^{m_1} z_2^{m_2} h$. It follows easily that $\tilde{v}_*$ maps $A \hat{\otimes} I$ isomorphically onto itself. A straightforward argument involving diagram chase now shows that $v_* : A \hat{\otimes} H^0(L_2; O) \to A \hat{\otimes} H^0(L_2; O)$ is an isomorphism. This completes the proof.

Assume that $P_i \subset G_i$ are maximal parabolics and the $\hat{L}_i$ are the negative ample generators of the $Pic(G_i/P_i) \cong \mathbb{Z}$. We have the following description of the principal $\mathbb{C}$-bundles over $S_\lambda(L)$. Let $z \neq 0$. Let $\{g_{ij}\}$ be a 1-cocycle defining the principal $\mathbb{C}$-bundle $L \to S_\lambda(L)$. Then the $\mathbb{C}$-bundle $L_z$ is the element $z[L] \in H^1(S_\lambda(L); O)$ is defined by the cocycle $\{z g_{ij}\}$ for any $z \in \mathbb{C}$. We denote the corresponding $\mathbb{C}$-bundle by $L_z$. Note that the total space and the projection are the same as that of $L$. The $\mathbb{C}$-action on $L_z$ is related to that on $L$ where $w.v \in L_z$ equals $(w/z).v = a_\lambda(w/z)(v) \in L$ for $w \in \mathbb{C}, v \in L$. The vector field corresponding to the $\mathbb{C}$-action on $L_z$ is given by $(1/z)v_\lambda$. Of course, when $z = 0$, $L_z$ is just the product bundle.

We shall denote the line bundle (i.e. rank 1 vector bundle) corresponding to $L_z$ by $E_z$. Observe that $E_z = L_z \times_\mathbb{C} \mathbb{C}$, where $(w.v.t) \sim (v, \exp(2\pi \sqrt{-1} w)t), w, t \in \mathbb{C}, v \in L_z$, when $z \neq 0$. If $z \neq 0$, any cross-section $\sigma : S_\lambda(E_z) \to E_z = L_z \times_\mathbb{C} \mathbb{C}$ corresponds to a holomorphic function $h_\sigma : L \to \mathbb{C}$ which satisfies the following:

$$
h_\sigma(w.v) = \exp(-2\pi \sqrt{-1} w) h_\sigma(v)
$$
for all $v \in L_z, w \in \mathbb{C}$. Equivalently, this means that $h_\sigma(\alpha_\lambda(w)v) = \exp(-2\pi\sqrt{-1}wz)h_\sigma(v)$ for $w \in \mathbb{C}$ and $v \in L$. This implies that

$$v_\lambda(h_\sigma) = -2\pi\sqrt{-1}zh_\sigma. \quad (11)$$

Conversely, if $h$ satisfies (11), then it determines a unique cross-section of $E_z$ over $S_\lambda(L)$.

We have the following result concerning the field of meromorphic functions on $S_\lambda(L)$ with diagonal type complex structure. The proof will be given after some preliminary observations.

**Theorem 4.8.** Let $L_i$ be the negative ample generator of $Pic(G_i/P_i) \cong \mathbb{Z}$ where $P_i$ is a maximal parabolic subgroup of $G_i$, $i=1,2$. Assume that $S_\lambda(L)$ is of diagonal type. Then the field $\kappa(S_\lambda(L))$ of meromorphic functions of $S_\lambda(L)$ is purely transcendental over $\mathbb{C}$. The transcendence degree of $\kappa(S_\lambda(L))$ is less than $\dim S_\lambda(L)$.

Let $U_i$ denote the opposite big cell, namely the $B_i^{-}$-orbit of $X_i = G_i/P_i$ the identity coset where $B_i^{-}$ is the Borel subgroup of $G_i$ opposed to $B_i$. One knows that $U_i$ is a Zariski dense open subset of $X_i$ and is isomorphic to $\mathbb{C}^{r_i}$ where $r_i$ is the number of positive roots in the unipotent part $P_{i,u}$ of $P_i$. The bundle $\pi_i : L_i \rightarrow X_i$ is trivial over $U_i$ and so $\tilde{U}_i := \pi_i^{-1}(U_i)$ is isomorphic to $\mathbb{C}^{r_i} \times \mathbb{C}^*$. We shall now describe a specific isomorphism which will be used in the proof of the above theorem.

Consider the projective imbedding $X_i \subset \mathbb{P}(V(\omega_i))$. Let $v_0 \in V(\omega_i)$ be a highest weight vector so that $P_i$ stabilizes $Cv_0$; equivalently, $\pi_i(v_0)$ is the identity coset in $X_i$. Let $Q_i \subset P_i$ be the isotropy at $v_0 \in V(\omega_i)$ for the $G_i$ so that $G_i/Q_i = L_i$. The Levi part of $P_i$ is equal to centralizer of a one-dimensional torus $Z$ contained in $T$ and projects onto $P_i/Q_i \cong \mathbb{C}^*$, the structure group of $L_i \rightarrow X_i$.

Let $F_i \in H^0(X_i;L_i^\vee) = V(\omega_i)^\vee$ be the lowest weight vector such that $F_i(v_0) = 1$. Then $U_i \subset X_i$ is precisely the locus $F_i \neq 0$ and $F_i|_{\pi_i^{-1}(v)} : C_v \rightarrow \mathbb{C}$ is an isomorphism of vector spaces for $v \in \tilde{U}_i$. We denote also by $F_i$ the restriction of $F_i$ to $\tilde{U}_i$.

Let $Y_\beta$ be the Chevalley basis element of $Lie(G_i)$ of weight $-\beta, \beta \in R^+(G_i)$. We shall denote by $X_\beta \in \text{Lie}(G_i)$ the Chevalley basis element of weight $\beta \in R^+(G_i)$. Recall that $H_\beta := [X_\beta,Y_\beta] \in \text{Lie}(T)$ is non-zero whereas $[X_\beta,Y_\beta] = 0$ if $\beta \neq \beta'$.

Let $R_{P_i} \subset R^+(G_i)$ denote the set of positive roots of $G_i$ complementary to positive roots of Levi part of $P_i$ and fix an ordering on it. (Thus $\beta \in R_{P_i}$ if and only if $-\beta$ is not a root of $P_i$.) Let $r_i = |R_{P_i}| = \dim X_i$. Then $\text{Lie}(P_{i,u}^-) \cong \mathbb{C}^{r_i}$ where $P_{i,u}^-$ denotes the unipotent radical of the parabolic opposed to $P_i$. Observe that $P_i \cap P_{i,u}^- = \{1\}$. The exponential map defines an algebraic isomorphism $\theta : \mathbb{C}^{r_i} \cong \text{Lie}(P_{i,u}^-) \rightarrow U_i$ where $\theta((y_\beta)_{\beta \in R_{P_i}}) = (\prod_{\beta \in R_{P_i}} \exp(y_\beta Y_\beta)).P_i \in G_i/P_i$. It is understood that, here and in the sequel, the product is carried out according to the ordering on $R_{P_i}$.

If $v \in Cv_0$, then $\theta$ factors through the map $\theta_v : \mathbb{C}^{r_i} \cong \text{Lie}(P_{i,u}^-) \rightarrow \tilde{U}_i$ defined by $(y_\beta)_{\beta \in R_{P_i}} \mapsto \prod \exp(y_\beta Y_\beta).v$. Moreover, $F_i$ is constant —equal to $F_i(v)$— on the image of $\theta_v$. 
We define $\tilde{\theta} : \mathbb{C}^r \times \mathbb{C}^* \cong \text{Lie}(P^{-}_{i}u) \times \mathbb{C}^* \cong P^{-}_{i}u \times \mathbb{C}^* \rightarrow \tilde{U}_i$ to be $\tilde{\theta}((y_\beta), z) = (\prod \exp(y_\beta Y_\beta)).z v_0 = \theta_{y,z}(y_\beta)).$ This is an isomorphism. We obtain coordinate functions $z, y_\beta, \beta \in R_{P_i}$ by composing $\tilde{\theta}^{-1}$ with projections $\mathbb{C}^r \times \mathbb{C}^* \rightarrow \mathbb{C}.$ Note that $F_i(\tilde{\theta}((y_\beta), z)) = z.$ Thus the coordinate function $z$ is identified with $F_i.$

Since $F_i$ is the lowest weight vector (of weight $-\omega_i),$ $Y_\beta F_i = 0$ for all $\beta \in R^+(G_i).$ Define $F_{i,\beta} := X_\beta(F_i), \beta \in R_{P_i}.$ Then $Y_\beta(F_{i,\beta}) = -[X_\beta, Y_\beta]F_i = -H_\beta(F_i) = \omega_i(H_\beta)F_i$ for all $\beta \in R_{P_i}.$ Note that $\omega_i(H_\beta) \neq 0$ as $H_\beta \in R_{P_i}.$ If $\beta', \beta \in R_{P_i}$ are unequal, then $Y_\beta F_{i,\beta} = 0.$ It follows that $Y^\mu_n(F_{i,\beta}) = 0$ unless $\beta' = \beta$ and $m = 1.$

The following result is well-known to experts in standard monomial theory. (See [12].)

**Lemma 4.9.** With the above notations, the map $\tilde{U}_i \rightarrow \mathbb{C}^r \times \mathbb{C}^*$ defined as $v \mapsto ((F_{i,\beta}(v))_{\beta \in R^+_i} : F_i(v), \ v \in \tilde{U}_i,$ is an algebraic isomorphism for $i = 1, 2.$

**Proof.** It is easily verified that $\partial f/\partial y_\beta|_{v_0} = Y_\beta(f)(v_0)$ for any local holomorphic function defined in a neighbourhood of $v_0.$ (Cf. [12].)

Let $y = \tilde{\theta}((y_\beta), z) = \prod_{\gamma \in R_{P_i}} \exp(y_\gamma Y_\gamma) \in P^{-}_{i}u.$ Denote by $l_y : \tilde{U}_i \rightarrow \tilde{U}_i$ the left multiplication by $y.$ If $v = y.v_0 \in \tilde{U}_i,$ then $(\partial/\partial y_\beta)_v(f) = (\partial/\partial y_\beta)|_{v_0}(f \circ l_y).$ Taking $f = F_{i,\beta}, \beta \in R_{P_i}$ a straightforward computation using the observation made preceding the lemma, we see that $(\partial/\partial y_\beta)_v(F_{i,\gamma}) = Y_\beta|_{v_0}(F_{i,\gamma} \circ l_y) = F_i(v) \omega_i(H_\beta)\delta_{\beta,\gamma}$ (Kronecker $\delta$). We also have $(\partial/\partial y_\beta)_v(F_{i}) = 0$ for all $v \in \tilde{U}_i.$ Hence $(\partial/\partial y_\beta)_v(F_{i,\gamma}/F_i) = \omega_i(H_\beta)\delta_{\beta,\gamma}.$

Thus the Jacobian matrix relating the $F_{i,\beta}/F_i$ and the $y_\beta, \beta \in R_{P_i}$, is a diagonal matrix of constant functions. The diagonal entries are non-zero as $\omega_i(H_\beta) \neq 0$ for $\beta \in R_{P_i}$ and the lemma follows. \hfill $\square$

We shall use the coordinate functions $F_{i,}, F_{i,\beta}, \beta \in R_{P_i},$ to write Taylor expansion for analytic functions on $\tilde{U}_i.$ In particular, the coordinate ring of the affine variety $\tilde{U}_i$ is just the algebra $\mathbb{C}[F_{i,\beta}, \beta \in R_{P_i}][F_i, F_i^{-1}].$ The projective normality [19] of $G_i/P_i$ implies that $\mathbb{C}[\tilde{L}_i] = \oplus_{r \geq 0} H^0(X_i; \tilde{L}_i^{-r}) = \oplus_{r \geq 0} V(\omega_i)^r.$ Since $\tilde{U}_i$ is defined by the non-vanishing of $F_i,$ we see that $\mathbb{C}[	ilde{U}_i] = \mathbb{C}[\tilde{L}_i][1/F_i].$

Now let $X = X_1 \times X_2$ and $\tilde{T} = \tilde{T}_1 \times \tilde{T}_2 \cong (\mathbb{C}^*)^N, N = n_1 + n_2,$ where the isomorphism is as chosen in §3. Let $d_i > 0, i = 1, 2,$ be chosen as in Proposition [3.1] so that the $\tilde{T}_i$-action on $L_i \rightarrow G_i/P_i$ is $d_i$-standard. Let $\lambda = \lambda_s \in \text{Lie}(\tilde{T}).$ Suppose that $\lambda$ satisfies the weak hyperbolicity condition of type $(n_1, n_2).$

Recall from (4) and (5) that for any weight $\mu_i \in \Lambda(\omega_i),$ there exist elements $\lambda_{\mu_1}, \lambda_{\mu_2} \in \mathbb{C}$ such that for any $v = (v_1, v_2) \in V_\mu_1(\omega_1) \times V_\mu_2(\omega_2),$ the $\alpha_\lambda$-action of $\mathbb{C}$ is given by $\alpha_\lambda(z)v = (\exp(z\lambda_{\mu_1})v_1, \exp(z\lambda_{\mu_2})v_2).$ In fact $\lambda_{\mu_i} = \sum_{n_{i-1} < j \leq n_{i-1} + n_1} d_{n_1, j} \lambda_j$ where $d_{n_1, j}$ are certain non-negative integers. It follows that, as observed in the discussion preceding the statement of Theorem [3.2], the complex numbers $\lambda_{\mu_i} \in \mathbb{C}, \mu_i \in \Lambda(\omega_i), i = 1, 2$ satisfy weak hyperbolicity condition:

$$0 \leq \arg(\lambda_{\mu_1}) < \arg(\lambda_{\mu_2}) < \pi, \ \forall \mu_i \in \Lambda(\omega_i), i = 1, 2.$$

(12)
Lemma 4.11. ∈

We observe that if $\mu = \mu_1 + \cdots + \mu_r = \nu_1 + \cdots + \nu_r$, where $\mu_j, \nu_j \in \Lambda(\omega_i)$, then $\lambda_{\mu,r} := \sum \lambda_{\mu_j} = \sum \lambda_{\nu_j}$. (This is a straightforward verification using (3) and (4).) Therefore, if $v \in V(\omega_i)^{\otimes r}$ is any weight vector of weight $\mu$, we get, for the diagonal action of $\mathbb{C}$, $z.v = \exp(\lambda_{\mu,r}z)v$.

Any finite dimensional $\tilde{G}_i$-representation space $V$ is naturally $\tilde{G}_1 \times \tilde{G}_2$-representation space and is a direct sum of its $\tilde{T}$-weight spaces $V_\mu$. If $V$ arises from a representation of $G_i$ via $\tilde{G}_i \to G_i$, then the $\tilde{T}$-weights of $V$ are the same as $T$-weights.

Definition 4.10. Let $Z_i(\lambda) \subset \mathbb{C}, i = 1, 2$, be the abelian subgroup generated by $\lambda_\mu, \mu \in \Lambda(\omega_i)$ and let $Z(\lambda) := Z_1(\lambda) + Z_2(\lambda) \subset \mathbb{C}$.

The $\lambda$-weight of an element $0 \neq f \in \text{Hom}(V_\mu(\omega_i); \mathbb{C})$ is defined to be $w_\lambda(f) := \lambda_\mu$. If $h \in \text{Hom}(V(\omega_i)^{\otimes r}; \mathbb{C})$ is weight vector of weight $-\mu$, (so that $h \in \text{Hom}(V_\mu(\omega_i)^{\otimes r}; \mathbb{C})$) we define the $\lambda$-weight of $v$ to be $\lambda_{\mu,r}$. If $f \in \text{Hom}(V_\mu(r\omega_i), \mathbb{C})$ is a weight vector (of weight $-\mu$), then it is the image of a unique weight vector $\tilde{f} \in \text{Hom}(V(\omega_i)^{\otimes r}, \mathbb{C})$ under the surjection induced by the $\tilde{G}_i$-inclusion $V(r\omega_i) \to V(\omega_i)^{\otimes r} = V(\omega_i) \oplus V'$ where $\tilde{f}|V' = 0$. We define the $\lambda$-weight of $f$ to be $w_\lambda(f) := w_\lambda(\tilde{f})$.

If $h_i \in V(r_i\omega_i)^{\nu_i} \subset \mathbb{C}[\hat{L}_i], i = 1, 2$, are weight vectors, then $h_1h_2$ is a weight vector of $V(r_1\omega_1)^{\nu_1} \otimes V(r_2\omega_2)^{\nu_2} \subset \mathbb{C}[\hat{L}_1 \times \hat{L}_2]$ and we have $w_\lambda(h_1h_2) = w_\lambda(h_1) + w_\lambda(h_2) \in Z(\lambda)$. Note that $w_\lambda(f_1 \cdots f_k) = \sum 1 \leq j \leq r w_\lambda(f_j) \in Z(\lambda)$ where $f_j \in \mathbb{C}[\hat{L}_1 \times \hat{L}_2] = \oplus_{r_1, r_2 \geq 0} V(r_1\omega_1)^{\nu_1} \otimes V(r_2\omega_2)^{\nu_2}$ are weight vectors.

Also $w_\lambda(f) \in Z(\lambda)$ is a non-negative linear combination of $\lambda_j, 1 \leq j \leq N$ for any $f \in \mathbb{C}[\hat{L}_1 \times \hat{L}_2]$.

If $f \in V(\omega_i)^{\nu_i}$, it defines a holomorphic function on $V(\omega_1) \times V(\omega_2)$ and hence on $L$, and denoted by the same symbol $f$; explicitly $f(u_1, u_2) = f(u_i), \forall (u_1, u_2) \in L$.

Lemma 4.11. We keep the above notations. Assume that $\lambda = \lambda_s \in \text{Lie}(\tilde{T}) = \mathbb{C}^N$.

Fix $\mathbb{C}$-bases $\mathcal{B}_i$ for $V(\omega_i)^{\nu_i}$, consisting of $\tilde{T}$-weight vectors. Let $z_0 \in Z(\lambda)$. There are only finitely many monomials $f := f_1 \cdots f_k, f_j \in \mathcal{B}_1 \cup \mathcal{B}_2$ having $\lambda$-weight $z_0$. Furthermore, $v_\lambda(f) = w_\lambda(f)f$.

Proof. The first statement is a consequence of weak hyperbolicity (see (12)). Indeed, since $0 \leq \arg(\lambda_\mu) < \pi$ for all $\mu \in \Lambda(\omega_i), i = 1, 2$, given any complex number $z_0$, there are only finitely many non-negative integers $c_j$ such that $\sum c_j\lambda_{\mu_j} = z_0$.

As for the second statement, we need only verify this for $f \in \mathcal{B}_i, i = 1, 2$. Suppose that $f \in \mathcal{B}_1$ and that $f$ is of weight $-\mu, \mu \in \Lambda(\omega_1)$, say. Then, for any $(u_1, u_2) \in L$, writing...
\[ u_1 = \sum_{\nu \in \Lambda(\omega_1)} u_\nu, \text{ using linearity and the fact that } f(u_1, u_2) = f(u_\mu) \text{ we have} \]
\[
 v_\lambda(f)(u_1, u_2) = \lim_{w \to 0}(f(\alpha_\lambda(w)(u_1, u_2)) - f(u_1, u_2))/w \\
 = \lim_{w \to 0}(f(\exp(\lambda w)u_\mu) - f(u_1))/w \\
 = \lim_{w \to 0}\left(\frac{\exp(\lambda w)-1}{w}\right)f(u_1) \\
 = \lambda_\mu f(u_1) \\
 = \lambda_\mu f(u_1, u_2). \]

This completes the proof. \[\square\]

We assume that \( F_i, F_{i,\beta}, \beta \in R_{P_i}, \text{ are in } B_i, \ i = 1, 2. \)

Let \( M \subset \mathbb{C}(\tilde{U}_1 \times \tilde{U}_2) \) denote the multiplicative group of all Laurent monomials in \( F_i, F_{i,\beta}, \beta \in R_{P_i}, i = 1, 2. \) One has a homomorphism \( wt_\lambda : M \to Z(\lambda) \).

\[ \text{Lemma 4.12. With the above notations, } wt_\lambda : M \to Z(\lambda) \text{ is surjective. Any } \mathbb{Z}\text{-basis } h_1, \ldots, h_k \text{ of } K \text{ is algebraically independent over } \mathbb{C}. \]

\[ \text{Proof. Suppose that } \nu \in Z_i(\lambda). \text{ Write } \nu = \sum a_\mu \lambda_\mu \text{ and choose } \nu = \sum b_\mu \in B_i \text{ to be of weight } \mu. \text{ Then } wt_\lambda(\prod \beta_{\mu}^{\nu}) = \nu. \text{ On the other hand, } wt_\lambda(b_\mu) \text{ equals the } \lambda\text{-weight of any monomial in the } F_i^{-1}, F_i, F_{i,\beta}, \beta \in R_{P_i} \text{ that occurs in } b_\mu \tilde{U}_i. \text{ The first assertion follows from this.} \]

Let, if possible, \( P(z_1, \ldots, z_k) = 0 \) be a polynomial equation satisfied by \( h_1, \ldots, h_k. \) Note that the \( h_j \) are certain Laurent monomials in a transcendence basis of the field \( \mathbb{C}(\tilde{U}_1 \times \tilde{U}_2) \) of \textit{rational functions} on the affine variety \( \tilde{U}_1 \times \tilde{U}_2. \) Therefore there must exist monomials \( z^m, z^{m'}, m \neq m', \) occurring in \( P(z_1, \ldots, z_k) \) with non-zero coefficients such that \( h^m = h^{m'} \in \mathbb{C}(\tilde{U}_1 \times \tilde{U}_2). \) Hence \( h^{m-m'} = 1. \) This contradicts the hypothesis that the \( h_j \) are linearly independent in the multiplicative group \( K. \) \[\square\]

We now turn to the proof of Theorem 4.8.

\[ \text{Proof of Theorem 4.8. By definition, any meromorphic function on } S_\lambda(L) \text{ is a quotient } f/g \text{ where } f \text{ and } g \text{ are holomorphic sections of a holomorphic line bundle } E_z. \text{ Any holomorphic section } f : S(L) \to E_z \text{ defines a holomorphic function on } L, \text{ denoted by } f, \text{ which satisfies Equation (11). By the normality of } \tilde{L}_1 \times \tilde{L}_2, \text{ the function } f \text{ then extends uniquely to a function on } \tilde{L}_1 \times \tilde{L}_2 \text{ which is again denoted } f. \text{ Thus we may write } f = \sum_{r,s \geq 0} f_{r,s} \text{ where } f_{r,s} \in V(r\omega_1)^{\nu} \otimes V(s\omega_2)^{\nu}. \text{ Now } v_\lambda f = af \text{ and } v_\lambda f_{r,s} \in V(r\omega_1)^{\nu} \otimes V(s\omega_2)^{\nu} \text{ implies that } v_\lambda(f_{r,s}) = af_{r,s} \text{ for all } r, s \geq 0 \text{ where } a = -2\pi \sqrt{-1}z. \text{ This implies that } wt_\lambda(f_{r,s}) = a \text{ for all } r, s \geq 0. \text{ This implies, by Lemma 4.11, that } f_{r,s} = 0 \text{ for sufficiently large } r, s \text{ and so } f \text{ is algebraic.} \]

Now writing \( f \) and \( g \) restricted to \( \tilde{U}_1 \times \tilde{U}_2 \) as a polynomial in the the coordinate functions \( F_i^\pm, F_{i,\beta}, i = 1, 2, \) introduced easily that \( f/g \) belongs to the field \( \mathbb{C}(\kappa) \) generated by \( \kappa. \) Evidently \( \kappa—\text{and hence the field } \mathbb{C}(\kappa)—\text{is contained in } \kappa(S_\lambda(L)). \) Therefore \( \kappa(S_\lambda(L)) \text{ equals } \mathbb{C}(\kappa). \) By Lemma 4.12 the field \( \mathbb{C}(\kappa) \) is purely transcendental over \( \mathbb{C}. \)
Finally, since $Z(\lambda)$ is of rank at least 2 and since $wt_\lambda: \mathcal{M} \to Z(\lambda)$ is surjective, 
$tr.deg(\kappa(S_\lambda(L))) = rank(K) \leq rank(K) - 2 = dim(L) - 2 = dim(S_\lambda(L)) - 1. \Box$

**Remark 4.13.** (i) We have actually shown that the transcendence degree of $\kappa(S_\lambda(L))$ equals the rank of $K$. In the case when $X_i$ are projective spaces, this was observed by [13]. When $\lambda$ is of scalar type, $tr.deg(\kappa(S_\lambda(L))) = dim(S_\lambda(L)) - 1.$

(ii) Theorem 4.8 implies that any algebraic reduction of $S_\lambda(L)$ is a rational variety. In the case of scalar type, one has an elliptic curve bundle $S_\lambda(L) \to X_1 \times X_2.$ (Cf. [22].) Therefore this bundle projection yields an algebraic reduction. In the general case however, it is an interesting problem to construct explicit algebraic reductions of these compact complex manifolds. (We refer the reader to [17] and references therein to basic facts about algebraic reductions.)

(iii) We conjecture that $\kappa(S_\lambda(L))$ is purely transcendental for $X_i = G_i/P_i$ where $P_i$ is any parabolic and $\bar{L}_i$ is any negative ample line bundle over $X_i$, where $S_\lambda(L)$ has any linear type complex structure.
