Structural and magnetic investigations of some new boron containing rare earth intermetallic compounds

S K MALIK, S K DHAR and R VIJAYARAGHAVAN
Tata Institute of Fundamental Research, Bombay 400005, India

Abstract. By alloying boron with RPD₃ (R = rare earth) compounds, new ternary alloys of the formula RPDₓBₓ (0 ≤ x ≤ 1) have been prepared. The parent RPD₃ compounds crystallise in the cubic AuCu₃ type structure. The addition of boron does not change the structure but results in an expansion of the lattice. Therefore, it is likely that the small boron atoms occupy the vacant body centred position in AuCu₃ type structure. It is also observed that compounds of the composition RR₃B can be formed in the cubic structure for all rare earths R though the parent RR₃ compounds exist only for R = Ce (AuCu₃ type) and La, Sm, Nd and Gd (all hexagonal CeNi₃ type). This points out the role of boron in stabilising new crystallographic phases. The results of susceptibility measurements on some of the RPD₃B and RR₃B compounds are presented. In particular, it is noted that while GdPD₃ orders antiferromagnetically with Tᵢ = 6 K, GdPDₓBₓ does not order magnetically down to 4.2 K.

Keywords. Boron: rare earths; magnetic susceptibility; structural investigations.

1. Introduction

During the last few years a new class of rare earth compounds known as rare earth ternary borides have attracted a great deal of attention. The interest in these compounds is due to their fascinating magnetic and superconducting properties. For example, in the series of ternary borides represented by the formula RR₃B₄ (R = rare earth), first synthesized by Matthias et al (1977a, b), the compounds with Th, Y, Nd, Sm, Er, Tm and Lu are superconducting whereas those with Gd, Tb, Dy and Ho undergo ferromagnetic ordering. Following the RR₃B₄ series of compounds, many other ternary borides forming at different stoichiometries have been synthesised and investigated for magnetic and possible superconducting behaviour. In this paper we report the formation of new boron containing rare earth compounds represented by the formula RPDₓBₓ (0 ≤ x ≤ 1) and RR₃B where R = La to Lu. Magnetic studies on some of these alloys are also presented.

An indication that alloys of the formula RR₃B₄ and RPDₓBₓ may well exist came first during the course of our investigations on RR₃B₂ compounds described elsewhere (Malik et al 1983). In the initial stages of our work on these, we observed, in the x-ray diffraction pattern of CeRh₃B₂, the existence of some extra lines which could not be ascribed to hexagonal CeRh₃B₂ compound. A careful analysis showed that these extra lines could be indexed on the basis of a cubic structure. The lattice constant of this cubic phase turned out to be slightly larger than that of CeRh₃ which crystallises in the cubic AuCu₃ structure type (Harris and Norman 1967). Because of the structural considerations of the AuCu₃ type crystal lattice, to be discussed below, the formula of this new cubic phase was presumed to be CeRhₓBₓ (0 < x ≤ 1). Subsequently we found that starting with appropriate amounts of Ce, Rh and B, cubic compounds having the formula CeRhₓBₓ (0 < x ≤ 1) could indeed be formed. The formation of alloys of the
above composition immediately suggested the likely existence of Rpd$_3$B$_x$ compounds. The Rpd$_3$ compounds also crystallise in the AuCu$_3$ structure type (Harris and Raynor 1965) with lattice constants comparable to that of CeRh$_3$. Later investigations (Dhar et al 1981a) verified the formation of Rpd$_3$B$_x$ ($0 < x < 1$) alloys for all the rare earths R. Further extension of the work showed that Rpd$_3$Si$_x$ alloys could also be formed, though silicon content is much smaller.

2. Rpd$_3$B$_x$ ($0 < x < 1$; R = Rare earth) alloys

2.1 Synthesis and structure

Master Rpd$_3$ alloys were first prepared by melting together stoichiometric amounts of the rare earth and the Pd metal in an arc furnace. The alloy ingots were turned and melted several times to ensure homogeneity. Approximately half the amount of each Rpd$_3$ alloy was remelted with an appropriate amount of boron in a water cooled copper boat in an induction furnace to form Rpd$_3$B alloys. This preliminary mixing of boron with Rpd$_3$ achieved by induction heating was necessary as otherwise boron chunks were found to shatter and fly away on coming under the arc in the arc furnace. In order to ensure complete mixing the fused charge of Rpd$_3$ and boron was remelted in the arc furnace. Alloy formation at the stoichiometry Rpd$_3$B$_x$ ($0 < x < 1$) was tried for few rare earths only, e.g. La, Ce, Pr, Eu, Gd and Dy and these were obtained by remelting appropriate proportions of Rpd$_3$ and Rpd$_3$B. In the case of europium and ytterbium compounds, excess amount of the rare earth was taken to compensate for the loss due to evaporation during melting. Powder x-ray diffraction patterns were recorded using CuK$_\alpha$ radiation.

The Rpd$_3$ compounds are known to crystallise in the cubic AuCu$_3$ type structure, space group Pm3m (figure 1a). The rare earth atoms occupy the cube corners and Pd atoms are on the face centred positions. The various atomic positions in the unit cell are given by (Pearson 1967)

![Graph showing x-ray diffraction patterns of NdPd$_3$ and some RPd$_3$B (R = Nd, Gd and Tb) compounds.]

![Graph showing lattice parameter of RPd$_3$B$_x$ (R = La, Pr, Gd and Dy) alloys as a function of boron concentration x.]

R  (1a)  $m3m$  :  0, 0, 0
Pd  (3c)  $4/mmm$  :  0, 1/2, 1/2; 1/2, 0, 1/2; 1/2, 1/2, 0.

The x-ray diffraction patterns of RPd$_3$B$_x$ (for all x) compounds are identical to that of the RPd$_3$ compounds (figure 2) and hence can be fitted to cubic structure type. However, the lattice parameter of the former is observed to be slightly larger than that of the parent RPd$_3$ compound and depends on the boron concentration x. Figure 3 shows the dependence of lattice parameter on boron concentration in some of these alloys. The relatively small boron atoms presumably occupy the vacant body-centred position in the RPd$_3$ unit cell to give rise to an $E2_1$ anti-perovskite arrangement, space group $Pm3m$ (figure 1b). Thus RPd$_3$B$_x$ alloys may be considered to result from “addition” of boron to parent RPd$_3$ compound. Many compounds which have the AuCu$_3$ type structure are known to accommodate smaller non-metallic elements like B, C, N, Si etc. at the body-centred position resulting in anti-perovskite compound formation (Gschneidner et al 1978). The various atomic positions in the RPd$_3$B unit cell are given by (Pearson 1967)

R  (1a)  $m3m$  :  0, 0, 0
Pd  (3c)  $4/mmm$  :  0, 1/2, 1/2; 1/2, 0, 1/2; 1/2, 1/2, 0.

B  (1b)  $m3m$  :  1/2, 1/2, 1/2.

Table 1 lists the lattice constants of RPd$_3$ and RPd$_3$B compounds and the same information is plotted graphically in figure 4. It should be noted that the expansion in the cell volume of Ce and Eu compounds is relatively larger. Because of the highly volatile nature of Yb, efforts to make single phase YbPd$_3$B did not succeed. However, the extra phase in the alloy is estimated to be less than 10%.

2.2 Magnetic susceptibility measurements

From figure 4 it is seen that with the exception of EuPd₃B, the lattice constant of other RPD₃B compounds follows the usual lanthanide contraction for trivalent rare earth ions. Susceptibility measurements carried out on some of these compounds, i.e. for R = Pr, Nd, Sm, Gd, Tb, Dy, Er and Tm, in the temperature range 77 to 300 K, confirm the trivalency of rare earth ions. For GdPd₃ and GdPd₃B susceptibility behaviour down to 4.2 K was recorded for reasons given below. (The addition of boron to CePd₃ and EuPd₃ results in unusual lattice expansion and changes the magnetic properties of Ce and Eu ions drastically; results are discussed elsewhere (Dhar et al 1981b; 1982).

With the exception of SmPd₃B all other RPD₃B compounds, investigated for magnetic behaviour, show a linear $\chi^{-1}$ vs $T$ behaviour (figures 5 and 6). The effective paramagnetic moments were determined by using the formula $\chi(T) = N\mu_{\text{eff}}^2/[3k_B(T - \theta_p)]$. The values of $\mu_{\text{eff}}$ thus obtained are seen to be almost equal to the free ion value for the trivalent state and are listed in table 2. Small $\theta_p$ values suggest that magnetic ordering in RPD₃B compounds may occur only at very low temperatures. The nonlinear behaviour of $\chi^{-1}$ vs $T$ observed in SmPd₃B (figure 6) is a

consequence of the temperature independent contribution arising due to narrow multiplet separation of Sm³⁺ ion.

Introduction of non magnetic boron in the RPD₃ compounds, besides expanding the lattice, will also change the electron concentration in the conduction band. Since RKKY interaction responsible for magnetic ordering in rare earth compounds is electron concentration-dependent, any change in the latter would be expected to modify the exchange interaction between the rare earth ions. Examples exist in literature where such effects have been found. For instance while the moment carrying trivalent rare earths RA₃ order ferromagnetically (except CeAl₂), the compound EuAl₂ in which Eu is divalent and, therefore, contributes one electron less to the conduction band, is
antiferromagnetic (Wallace 1973). In the pseudobinary \( \text{Eu}_x \text{La}_{1-x} \text{Al}_2 \) a reversal in the magnetic coupling from antiferromagnetic to ferromagnetic with increasing \( x \), which alters the electron concentration, is observed (Mader and Wallace 1968). Similarly while GdAg and GdIn order antiferromagnetically with Neel temperatures of 145 K and 28 K respectively, the pseudobinary solutions GdAg\(_x\)In\(_{1-x}\) exhibit ferromagnetism for \( 0.8 < x < 0.3 \) with Curie temperature increasing with increasing \( x \) (Sekizawa and Yasukochi 1966). The dependence of exchange interaction on the electron concentration can be understood from the formula

\[
\theta_p = -\frac{3\pi Z^2 |J(0)|^2}{k_B E_F} S(S + 1) \sum_i F(2k_F r_i),
\]

where \( \theta_p \) is the paramagnetic Curie temperature, \( Z \) is the average number of conduction electrons per atom, \( 2J(0) \) is the exchange interaction constant between the rare earth spin \( S \) and conduction electron spin \( s \), \( E_F \) is the Fermi energy and \( F(x) = (x \cos x - \sin x)/x^4 \). In the molecular field approximation \( \theta_p \) is identical with the magnetic ordering temperature. The sign of \( F(x) \) determines the kind of magnetic order that develops: antiferromagnetic if sum is positive and ferromagnetic if the sum is negative. With the increase in electron concentration, \textit{i.e.} an increase in \( Z \) and hence in \( k_F \) (assuming crystal structure remains the same) \( x \) increases and \( F(x) \) shows an oscillatory behaviour from positive to negative values.

In order to see if the addition of boron is accompanied with any electron concentration effects, magnetic behaviour of GdPd\(_3\) and GdPd\(_3\)B was studied down to liq.He temperature. The compound GdPd\(_3\) was chosen because it is the only compound in the RPd\(_3\) series that orders magnetically above 4.2 K (Gardner \textit{et al} 1972). Figure 7 shows the magnetisation as a function of temperature in GdPd\(_3\) and GdPd\(_3\)B. In an external field of 4 kOe magnetisation of GdPd\(_3\) shows a sharp singularity at \( \sim 6 \) K which corresponds to an antiferromagnetic ordering in this compound. No such feature is observed in GdPd\(_3\)B which continues to remain paramagnetic down to 4.2 K. These observations show that the addition of boron modifies the exchange interaction

![Figure 7](image-url)  
\textbf{Figure 7.} The inverse susceptibility of GdPd\(_3\) and GdPd\(_3\)B as a function of temperature. The inset shows the temperature dependence of magnetization (in a field of 4 kOe).
between the rare earth ions either due to lattice expansion, or by changing electron concentration or a combination of both. Extension of magnetisation below 4.2K may, perhaps, show evidence of magnetic ordering in GdPd$_3$B.

3. RRh$_3$B compounds

3.1 Synthesis and structure

In the beginning of this paper we mentioned that alloys of the formula CeRh$_3$B$_x$ could be formed. This observation together with the fact that alloys of the composition RPd$_3$B$_x$ exist for all R prompted us to investigate whether single phase RRh$_3$B$_x$ alloys could be synthesised. It was found that RRh$_3$B compounds, do indeed, form for all rare earths R. The x-ray diffraction patterns of RRh$_3$B compounds (figure 8) are similar to those of RPd$_3$B compounds. Therefore, presumably RRh$_3$B compounds also crystallise in the anti-perovskite or filled AuCu$_3$ type structure. It may be noted that while the parent RPd$_3$B compounds exist for all R, such is not the case with RRh$_3$B compounds. The latter form only for R = Ce (AuCu$_3$ type structure) and La, Sm, Nd and Gd (hexagonal CeNi$_3$ type structure) (Landelli and Palenzona 1979). The non-metallic element boron, therefore, has the effect of stabilising the cubic RRh$_3$B phase. In fact, while our experimental investigations were on, we came across instances in the literature where complex metallic phases are stabilised by atoms like C, B, N, Si etc (Stadelmaier 1979). The alloys of composition RRh$_3$C$_x$ (x ~ 1) for all R also exist in the perovskite structure (Holleck 1971), thus strengthening our conclusions, reached independently by us, about the crystal structure of RRh$_3$B compounds.

In contrast to RPd$_3$B$_x$ alloys where 0 < x ≤ 1, it appears that RRh$_3$B$_x$ compounds do not form below a certain minimum concentration of boron (CeRh$_3$B$_x$ being an exception). Thus for x = 0.5 no perovskite formation was observed for R = La, Nd, and Er. Though, this was not tested for other rare earths we believe similar considerations should hold. We have not determined the minimum value of x for which RRh$_3$B$_x$ alloys can be stabilised.

Figure 8. The x-ray diffraction patterns of some RRh$_3$B (R = La, Ce, Gd and Er) compounds. These patterns can be indexed on the basis of a cubic unit cell.
3.2 Magnetic susceptibility and $^{151}$Eu Mössbauer measurements

The lattice constants of RRh$_3$B compounds are plotted in figure 9. With the exception of CeRh$_3$B, the usual lanthanide contraction with no anomaly in the lattice parameter is observed. This points out the trivalent character of rare earth ions in these compounds. This has been verified from susceptibility measurements carried out on some of these compounds in the temperature range 300 to 77 K. The $\chi^{-1}$ vs $T$ plots are shown in figures 10 and 11. For SmRh$_3$B $\chi^{-1}$ vs $T$ is non-linear for reasons similar to those given for SmPd$_3$B. The effective paramagnetic moments (very close to free ion value) and paramagnetic Curie temperatures are listed in table 2.

In case of EuRh$_3$B, the trivalency of Eu has been confirmed from $^{151}$Eu Mössbauer spectroscopy. A single Mössbauer absorption with isomer shift of 2.4 ± 0.1 mm/sec, characteristic of trivalent Eu in metallic environments, is observed at 300 K (figure 12). There is no change in isomer shift on lowering the temperature to 88 K.
4. Silicon addition to RPD₃ compounds

From the structural considerations of the RPD₃ unit cell mentioned above, we concluded that the small boron atoms in the RPD₃Bₓ alloys occupy the interstitial vacant body-centred position. It was, therefore, natural to investigate whether other non-metallic elements could be introduced in the RPD₃ lattice. In this direction we tried the synthesis of RPD₃Siₓ alloys for R = La, Ce and Eu only. It was found that like boron, silicon can also be alloyed with RPD₃ compounds. However, the atomic percentage of silicon that can be dissolved into RPD₃ lattice is far less than that of boron. Only up to x ~ 0.3, single phase cubic alloys were obtained for RPD₃Siₓ composition. This may be related to the relatively larger atomic volume of silicon compared to that of boron. From volume filling considerations alone it may not be possible to accommodate as many number of silicon atoms as boron. The addition of silicon, like boron, to parent RPD₃ compound leads to lattice expansion. Results of magnetic susceptibility and ¹⁵¹Eu Mössbauer spectroscopy on CePD₃Siₓ and EuPD₃Siₓ, where a valence change of Ce and Eu ions is observed on alloying with Si, are presented elsewhere (Malik et al 1982; Dhar et al 1983).

Carbon addition to RPD₃ compounds was also tried and it was found that carbon cannot be alloyed with RPD₃ compounds.
