Strategies to stabilize exohedral η^5 - and η^6 -fullerene transition metal organometallic complexes: A molecular orbital treatment

E. D. Jemmis* and M. Manoharan

School of Chemistry, University of Hyderabad, Hyderabad 500 046, India

Transition metal fragments are designed to overcome the unfavourable interaction arising from the splayed-out π -orbitals of the five- and six-membered rings of C₆₀ in complex formation. Semiemprical studies at the PM3(tm) level on a series of C₆₀MC_nH_n complexes suggest that, with the appropriate transifragments can be controlled to a large extent by the ligands around it. For example, the diffuse nature of the fragment orbitals increases on going from η^6 -C₆H₆M to η^3 -C₃H₃M (Figure 1)²⁶. In any such exercise, the electron count that is necessary to form a stable electronic structure has to be maintained. Hence, we selected the complexes of C₆₀ and C₆₀H₅⁻ (refs 27, 28) with metal fragments C_nH_nM (n = 3-6; M = transition metal) for theoretical study. The structures (1-14) studied here are given in Figure 2.

In view of the number and size of the molecules involved, the semiempirical MO method PM3(tm) with the parameters for transition metal provided by Hehre *et al.* is used for all calculations^{29,30}. The reliability of the method is tested for both geometry and energy of ex-

tion metal fragment, it is possible to stabilize η^6 complexes of C_{60} . Isodesmic equations of the type $C_m H_m M C_n H_n + C_{60} \rightarrow C_{60} M C_n H_n + C_m H_m$ indicate that $C_3 H_3 Co$ and $C_3 H_3 Rh$ are ideal fragments in stabilizing $\eta^6 \cdot C_{60}$ complexes. In comparison, η^5 complexes are less favourable; structural modifications such as those in the recently synthesized $C_{60} Ph_5$ should readily help η^5 -bonding.

WITH their five- and six-membered rings, it is tempting to speculate a rich organometallic chemistry for fullerenes along the same lines as ferrocene $(C_2H_5)_2Fe$ and dibenzene chromium $(C_6H_6)_2Cr$. However, the transition metal organometallic chemistry of fullerenes, so far, is dominated by η^2 -bonding¹⁻¹⁴ akin to olefin complexes. η^5 - and η^6 -complexes involving the five- and six-membered rings of fullerenes are unknown¹⁵⁻¹⁸. The propensity for η^2 -complexes is readily understood from the strain energy release involved in the complex formation; the geometry around carbon in C_{60} is remarkably close to that in the olefin complex^{19,20}. On the other hand, the decreased overlap of the splayed out orbitals of five- and six-membered rings of C_{60} with the frontier orbitals of transition metal fragments makes η^{3} - and η^{6} complexes unfavourable^{20,21}. The only η^6 -organometallic complex reported for a curved polyaromatic hydrocarbon involved corannulene which is much less curved than C_{60} (ref. 22). We present here ways to enhance the overlap of transition metal fragment orbitals with the five- and six-membered rings of C_{60} and predict viable targets for synthesis based on theoretical studies. The rigid structure of C_{60} (refs 23-25) cluster does not permit many avenues to enhance exohedral η^5 - and η° -bonding without dramatic alterations in the structure. Therefore, we concentrate on the metal fragment first. If the frontier orbitals of the transition metal fragments can be made more diffuse, the overlap with the splayed out orbitals of five- and six-membered rings can be improved. The frontier orbitals of transition metal

perimentally known complexes. Figure 3 shows crucial geometric parameters computed using PM3(tm) and found experimentally for $C_3H_3Co(CO)_3$, $C_4H_4Fe(CO)_3$, $C_5H_5Mn(CO)_3$ and $C_6H_6Cr(CO)_3$ or its derivatives³¹⁻³⁴. These are in reasonable agreement. A check on the reliability of energetics at this level is made by comparing the experimental value of the energy of the following reaction with the computed value (eq. 1)³⁵. The calculated value of 6.1 kcal/mol is in good accordance with the experimental value of 4.5 kcal/mol (ref. 36). This is also comparable to the estimate of 2.1 kcal/mol made using the PRDDO method²¹. Similar isodesmic equations³⁷ are used to estimate the improvements brought by various transition metal fragments in binding to fullerene.

 $C_{6}H_{6}Cr(CO)_{3} + C_{6}H_{5}Cl \rightarrow \eta^{6} - C_{6}H_{5}ClCr(CO)_{3} + C_{6}H_{6};$ $\Delta E = 6.1 \text{ kcal/mol} \qquad (1)$

Let us consider the isodesmic eqs (2)–(5) that involve η^6 -C₆₀ complex. As anticipated, dibenzenechromium is

*For correspondence. (c-mail: jemmis@uohyd.ernet.in)

considerably more favourable than η^6 -C₆₀CrC₆H₆(1) (eq. 2). The endothermicity of the reactions decreases from 30.8 kcal/mol with η^6 -C₆H₆M to 1.6 kcal/mol with η^3 -C₃H₃M. Evidently, the diffuse frontier orbitals of η^3 -C₃H₃Co help in increasing the interaction with C₆₀. Additional enhancement of diffuse nature of the metal fragment orbitals is achieved by going down the periodic

should be able to support η^6 -complexes of C₆₀. The structure of η^6 -C₆₀RhC₃H₃(5) shown in Figure 4 presents an interesting conformational problem. The C-C bonds of a six-membered ring in C₆₀ are not equal in length³⁸. This leads to three distinct arrangement **a**, **b** and **c** (Figure 4). The conformation **a** is calculated to be more favourable than **b** by 2.8 kcal/mol. This is true with the qualitative results available on C₆H₆M(CO)₃ complexes³⁹. Conformation **c** goes to **a** on optimization. The geometric parameters (Figure 2) calculated for various structures follow expected trends.

Figure 4. Computed structure of η^6 -C₆₀RhC₃H₃ complex (5). The structures **a**, **b** and **c** represent the orientation of C₃H₃ in relation to the six-membered ring of C₆₀; **a** is found to be lower in energy than **b** by 2.8 kcal/mol.

for C₆₀ as an η^5 -six-electron ligand. These complexes are calculated to have the charges of + 0.144 and + 0.077 respectively in the C₅₅ unit. C₆₀ is forced to be an η^5 -fourelectron donor in η^5 -C₆₀FeC₆H₆(8) and η^5 -C₆₀CoC₅H₅(9) and hence the C₅₅ unit in these complexes are calculated to have -0.495 and -0.167 charge respectively. None of these complexes are favourable in relation to the isolated C₆₀ and the corresponding metallocene; eqs (8)-(11) are all endothermic, by larger magnitudes than those of comparable eqs (2) and (3) involving η^6 -C₆₀.

From the point of view of ring-size and π -metal orbitaloverlap alone η^5 -C₆₀ should be better than η^6 -C₆₀ in binding to transition metal fragments. The angle subtended by a C-C bond with the plane of five- and six-membered rings are found to be 31.7° and 35.3° respectively³⁸. Thus, the π -orbitals of the five-membered face should be less unfavourable than those of the six-membered face. However, η^5 -C₆₀ binding brings in some constraints of electron counting. If the C₅ ring in C₆₀ forms an η^5 -complex, the remaining C₅₅ atoms will be left as an open shell system. This was not so with the η^6 -C₆₀ complexes. A closed shell C₅₅ unit can be obtained by forcing the η^5 -C₆₀ to bind either as a 4-electron donor leaving a formal C₅₅⁻ unit or as a 6-electron donor with a formal C₅₅⁺ unit. η^5 -C₆₀CrC₆H₆(6) and η^5 -C₆₀MnC₅H₅(7) constitute examples

$$C_6H_6CrC_6H_6 + C_{60} \rightarrow \eta^5 - C_{60}CrC_6H_6[6] + C_6H_6;$$

$$\Delta E = 56.7 \text{ kcal/mol} \qquad (8)$$

$$C_{5}H_{5}MnC_{6}H_{6} + C_{60} \rightarrow \eta^{5} - C_{60}MnC_{5}H_{5}[7] + C_{6}H_{6};$$

$$\Delta E = 46.9 \text{ kcal/mol} \qquad (9)$$

$$C_6H_6FeC_4H_4 + C_{60} \rightarrow \eta^5 - C_{60}FeC_6H_6[8] + C_4H_4;$$

 $\Delta E = 42.2 \text{ kcal/mol}$ (10)

$$C_5H_5C_0C_4H_4 + C_{60} \rightarrow \eta^5 - C_{60}C_0C_5H_5[9] + C_4H_4;$$

$$\Delta E = 52.0 \text{ kcal/mol} \qquad (11)$$

Obviously, the overlap factor alone cannot explain these results. A possible explanation comes from the electronic structure of C_{60} itself⁴⁰⁻⁴⁵; the delocalization of electrons in C_{60} is dominated by the C_6 rings^{25,46-48}. The pentagon isolation rule is a direct consequence of the meagre contribution of the valence bond configurations involving double bonds within the five-membered rings to the electronic structure of C_{60} (refs 40-45). The fivemembered ring is not naturally available to participate in bonding as a conventional cyclopentadienyl unit. Forcing the C_5 unit to act a penta-hapto ligand perturbs the electronic structure considerably and hence the $C_4H_4C_0C_5H_5 + C_{60}H_6 \rightarrow \eta^5 - C_{60}H_5C_0C_4H_4[12] + C_5H_6;$ $\Delta E = -14.3 \text{ kcal/mol}$ (19)

$$C_{3}H_{3}NiC_{5}H_{5} + C_{60}H_{6} \rightarrow \eta^{5}-C_{60}H_{5}NiC_{3}H_{3}[13] + C_{5}H_{6};$$

$$\Delta E = -17.3 \text{ kcal/mol}$$
(20)

$$C_{3}H_{3}PdC_{5}H_{5} + C_{60}H_{6} \rightarrow \eta^{5} - C_{60}H_{5}PdC_{3}H_{3}[10] + C_{5}H_{6};$$

$$\Delta E = -30.9 \text{ kcal/mol} \qquad (21)$$

$$C_{6}H_{6}MnC_{5}H_{5} + \eta^{5} - C_{60}H_{5}Li \rightarrow \eta^{5} - C_{60}H_{5}MnC_{6}H_{6}[10] + C_{5}H_{5}Li;$$

$$\Lambda F = -12.2 \text{ keel/mel} \qquad (22)$$

complexes are not favourable. One of the ways of overcoming the dilemma of the open shell C_{55} unit faced above is to form derivatives of C_{60} such as the recently synthesized $\eta^5 \cdot C_{60}$ Ph₅T1 (ref. 28). This has a regular fivemembered ring which can act as an isolated cyclopentadienyl anion. We have examined the η^5 -complexes of $C_{60}H_5^-(10-14)$. Equations (12)–(16) are endothermic, but this is more due to the extra stabilization anticipated for a large ion vs a small ion. However, even here the advantage of using metal fragments with more diffuse orbitals is clear as found in η^6 -C₆₀ complexes. A heavier metal reduces the endothermicity; eq. (16) is almost thermoneutral.

 $C_{6}H_{6}MnC_{5}H_{5} + C_{60}H_{5}^{-} \rightarrow \eta^{5} - C_{60}H_{5}MnC_{6}H_{6}[10] + C_{5}H_{5}^{-};$ $\Delta E = 32.6 \text{ kcal/mol} \qquad (12)$

 $C_5H_5FeC_5H_5 + C_{60}H_5^- \rightarrow \eta^5 - C_{60}H_5FeC_5H_5[11] + C_5H_5^-;$

 $\Delta \mathcal{L} = -12.2 \text{ kcal/mol} \qquad (22)$

$$C_{5}H_{5}FeC_{5}H_{5} + \eta^{5}-C_{60}H_{5}Li \rightarrow$$

$$\eta^{5}-C_{60}H_{5}FeC_{5}H_{5}[11] + C_{5}H_{5}Li;$$

$$\Delta E = -6.4 \text{ kcal/mol}$$
(23)

$$C_{4}H_{4}CoC_{5}H_{5} + \eta^{5} - C_{60}H_{5}Li \rightarrow$$

$$\eta^{5} - C_{60}H_{5}CoC_{4}H_{4}[12] + C_{5}H_{5}Li;$$

$$\Delta E = -21.1 \text{ kcal/mol}$$
(24)

$$C_{3}H_{3}NiC_{5}H_{5} + \eta^{5} - C_{60}H_{5}Li \rightarrow$$

$$\eta^{5} - C_{60}H_{5}NiC_{3}H_{3}[13] + C_{5}H_{5}Li;$$

$$\Delta E = -24.1 \text{ kcal/mol} \qquad (25)$$

$$C_{3}H_{3}PdC_{5}H_{5} + \eta^{5} - C_{60}H_{5}Li \rightarrow \\\eta^{5} - C_{60}H_{5}PdC_{3}H_{3}[14] + C_{5}H_{5}Li; \\\Delta E = -37.8 \text{ kcal/mol}$$
(26)

 $\Delta E = 38.1 \text{ kcal/mol} \qquad (13)$

 $C_4H_4C_0C_5H_5 + C_{60}H_5^- \rightarrow \eta^5 - C_{60}H_5C_0C_4H_4[12] + C_5H_5^-;$ $\Delta E = 23.7 \text{ kcal/mol}$ (14)

 $C_{3}H_{3}NiC_{5}H_{5} + C_{60}H_{5}^{-} \rightarrow \eta^{5}-C_{60}H_{5}NiC_{3}H_{3}[13] + C_{5}H_{5}^{-};$ $\Delta E = 20.7 \text{ kcal/mol}$ (15)

 $C_{3}H_{3}PdC_{5}H_{5} + C_{60}H_{5}^{-} \rightarrow \eta^{5}-C_{60}H_{5}PdC_{3}H_{3}[14] + C_{5}H_{5}^{-};$ $\Delta E = 7.0 \text{ kcal/mol}$ (16)

The effect of the inherent extra stability of the larger ion, $C_{60}H_5^-$, can be removed by employing the corresponding protonated species in the equations. For example, when these reactions are calculated with $C_{60}H_6$ and C_5H_6 instead of $C_{60}H_5^-$ and $C_5H_5^-$, the reactions (eqs (17)-(21)) are found to be more favourable. Similar esWe conclude that C_3H_3M fragments would provide largely diffuse frontier orbitals to stabilize the η^6 -C₆₀ transition metal complexes. Isodesmic equations indicate that η^6 -C₆₀RhC₃H₃ (Figure 4) should be one of the best possibilities. η^5 -C₆₀ complexes are more unfavourable. Structural modifications such as the recently synthesized C₆₀Ph₅⁻ would help to form η^5 -complexes.
