# ON THE FIELDS GENERATED BY THE LENGTHS OF CLOSED GEODESICS IN LOCALLY SYMMETRIC SPACES 

GOPAL PRASAD AND ANDREI S. RAPINCHUK

## 1. Introduction

This paper is a sequel to our paper [13] where we introduced the notion of weak commensurability of Zariski-dense subgroups of semi-simple algebraic groups and used our analysis of this relationship to answer some differential-geometric questions about length-commensurable and isospectral locally symmetric spaces that have received considerable amount of attention in recent years (cf. 3], 15]; a detailed survey is given in [12]). More precisely, given a Riemannian manifold $M$, the (weak) length spectrum $L(M)$ is the set of lengths of all closed geodesics in $M$, and two Riemannian manifolds $M_{1}$ and $M_{2}$ are said to be iso-length if $L\left(M_{1}\right)=L\left(M_{2}\right)$, and length-commensurable if $\mathbb{Q} \cdot L\left(M_{1}\right)=\mathbb{Q} \cdot L\left(M_{2}\right)$. It was shown in [13] that length-commensurability has strong consequences, one of which is that length-commensurable arithmetically defined locally symmetric spaces of certain types are necessarily commensurable, i.e. they have a common finite-sheeted cover. In the current paper, we will study the following two interrelated questions: Suppose that (locally symmetric spaces) $M_{1}$ and $M_{2}$ are not length-commensurable. Then
(1) How different are the sets $L\left(M_{1}\right)$ and $L\left(M_{2}\right)$ (or the sets $\mathbb{Q} \cdot L\left(M_{1}\right)$ and $\left.\mathbb{Q} \cdot L\left(M_{2}\right)\right)$ ?
(2) Can $L\left(M_{1}\right)$ and $L\left(M_{2}\right)$ be related in any reasonable way?

One can ask a variety of specific questions that fit the general framework provided by (1) and (2): for example, can $L\left(M_{1}\right)$ and $L\left(M_{2}\right)$ differ only in a finite number of elements, in other words, can the symmetric difference $L\left(M_{1}\right) \Delta L\left(M_{2}\right)$ be finite? Regarding (2), the relationship between $L\left(M_{1}\right)$ and $L\left(M_{2}\right)$ that makes most sense geometrically is that of similarity, requiring that there be a real number $\alpha>0$ such that

$$
L\left(M_{2}\right)=\alpha \cdot L\left(M_{1}\right) \quad\left(\text { or } \mathbb{Q} \cdot L\left(M_{2}\right)=\alpha \cdot \mathbb{Q} \cdot L\left(M_{1}\right)\right),
$$

which geometrically means that $M_{1}$ and $M_{2}$ can be made iso-length (resp., lengthcommensurable) by scaling the metric on one of them. At the same time, one can consider more general relationships with less apparent geometric context like polynomial equivalence which means that there exist polynomials $p\left(x_{1}, \ldots, x_{s}\right)$ and $q\left(y_{1}, \ldots, y_{t}\right)$ with real coefficients such that for any $\lambda \in L\left(M_{1}\right)$ one can find $\mu_{1}, \ldots, \mu_{s} \in L\left(M_{2}\right)$ so that $\lambda=p\left(\mu_{1}, \ldots, \mu_{s}\right)$, and conversely, for any $\mu \in L\left(M_{2}\right)$ there exist $\lambda_{1}, \ldots, \lambda_{t} \in$ $L\left(M_{1}\right)$ such that $\mu=q\left(\lambda_{1}, \ldots, \lambda_{t}\right)$. Our results show, in particular, that for most
arithmetically defined locally symmetric spaces the fact that they are not lengthcommensurable implies that the sets $L\left(M_{1}\right)$ and $L\left(M_{2}\right)$ differ very significantly and in fact cannot be related by any generalized form of polynomial equivalence (cf. \$77).

To formalize the idea of "polynomial relations" between the weak length spectra of Riemannian manifolds, we need to introduce some additional notations and definitions. For a Riemannian manifold $M$, we let $\mathscr{F}(M)$ denote the subfield of $\mathbb{R}$ generated by the set $L(M)$. Given two Riemannian manifolds $M_{1}$ and $M_{2}$, for $i \in\{1,2\}$, we set $\mathscr{F}_{i}=\mathscr{F}\left(M_{i}\right)$ and consider the following condition
$\left(T_{i}\right)$ the compositum $\mathscr{F}_{1} \mathscr{F}_{2}$ has infinite transcendence degree over the field $\mathscr{F}_{3-i}$.
In simple terms, the fact that condition $\left(T_{i}\right)$ holds means that $L\left(M_{i}\right)$ contains "many" elements which are algebraically independent of all the elements of $L\left(M_{3-i}\right)$. The goal of this paper is to prove that $\left(T_{i}\right)$ indeed holds for at least one $i \in\{1,2\}$ in various situations where $M_{1}$ and $M_{2}$ are pairwise non-length-commensurable locally symmetric spaces. These results can be used to prove a number of results on the nonexistence of nontrivial dependence between the weak length spectra along the lines indicated above - cf. 87. Here we only mention that $\left(T_{i}\right)$ implies the following condition
$\left(N_{i}\right) L\left(M_{i}\right) \not \subset A \cdot \mathbb{Q} \cdot L\left(M_{3-i}\right)$ for any finite set $A$ of real numbers,
which informally means that the weak length spectrum of $M_{i}$ is "very far" from being similar to the length spectrum of $M_{3-i}$.

To give the precise statements of our main results, we need to fix some notations most of which will be used throughout the paper. Let $G_{1}$ and $G_{2}$ be connected absolutely almost simple real algebraic groups such that $\mathcal{G}_{i}:=G_{i}(\mathbb{R})$ is noncompact for both $i=1$ and 2. (In $\S \S 2-5$ we will assume that both $G_{1}$ and $G_{2}$ are of adjoint type.) We fix a maximal compact subgroup $\mathcal{K}_{i}$ of $\mathcal{G}_{i}$, and let $\mathfrak{X}_{i}=\mathcal{K}_{i} \backslash \mathcal{G}_{i}$ denote the associated symmetric space. Furthermore, let $\Gamma_{i} \subset \mathcal{G}_{i}$ be a discrete torsion-free Zariski-dense subgroup, and let $\mathfrak{X}_{\Gamma_{i}}:=\mathfrak{X}_{i} / \Gamma_{i}$ be the corresponding locally symmetric space. Set $M_{i}=\mathfrak{X}_{\Gamma_{i}}$ and $\mathscr{F}_{i}=\mathscr{F}\left(M_{i}\right)$. We also let $K_{\Gamma_{i}}$ denote the subfield of $\mathbb{R}$ generated by the traces $\operatorname{Tr} \operatorname{Ad} \gamma$ for $\gamma \in \Gamma_{i}$. Let $w_{i}$ be the order of the (absolute) Weyl group of $G_{i}$.

Before formulating our results, we need to emphasize that the proofs assume the validity of Schanuel's conjecture in transcendental number theory (cf. 97), making the results conditional.

Theorem 1. Assume that the subgroups $\Gamma_{1}$ and $\Gamma_{2}$ are finitely generated (which is automatically the case if these subgroups are actually lattices).
(1) If $w_{1}>w_{2}$ then ( $T_{1}$ ) holds;
(2) If $w_{1}=w_{2}$ but $K_{\Gamma_{1}} \not \subset K_{\Gamma_{2}}$ then again ( $T_{1}$ ) holds.

Thus, unless $w_{1}=w_{2}$ and $K_{\Gamma_{1}}=K_{\Gamma_{2}}$, condition $\left(T_{i}\right)$ holds for at least one $i \in\{1,2\}$.
(We recall that $w_{1}=w_{2}$ implies that either $G_{1}$ and $G_{2}$ are of the same Killing-Cartan type, or one of them is of type $B_{n}$ and the other of type $C_{n}$ for some $n \geqslant 3$.)

Much more precise results are available when the groups $\Gamma_{1}$ and $\Gamma_{2}$ are arithmetic (cf. [13], §1, and $\$ 5$ below regarding the notion of arithmeticity). As follows from

Theorem 1, we only need to consider the case where $w_{1}=w_{2}$ which we will assume. Then it is convenient to divide our results into three theorems, two of which treat the case where $G_{1}$ and $G_{2}$ are of the same Killing-Cartan type, and the third one the case where one of the groups is of type $B_{n}$ and the other of type $C_{n}$ for some $n \geqslant 3$ (we note that the combination of these three cases covers all possible situations where $w_{1}=w_{2}$ ). When $G_{1}$ and $G_{2}$ are of the same type, we consider separately the cases where the common type is not one of the following: $A_{n}, D_{2 n+1}(n>1)$ and $E_{6}$ and where it is one of these types.

Theorem 2. Notations as above, assume that $G_{1}$ and $G_{2}$ are of the same KillingCartan type which is different from $A_{n}, D_{2 n+1}(n>1)$ and $E_{6}$ and that the subgroups $\Gamma_{1}$ and $\Gamma_{2}$ are arithmetic. Then either $M_{1}=\mathfrak{X}_{\Gamma_{1}}$ and $M_{2}=\mathfrak{X}_{\Gamma_{2}}$ are commensurable, hence $\mathbb{Q} \cdot L\left(M_{1}\right)=\mathbb{Q} \cdot L\left(M_{2}\right)$ and $\mathscr{F}_{1}=\mathscr{F}_{2}$, or conditions $\left(T_{i}\right)$ and $\left(N_{i}\right)$ hold for at least one $i \in\{1,2\}$.
(We note that $\left(T_{i}\right)$ and $\left(N_{i}\right)$ may not hold for both $i=1$ and 2 ; in fact it is possible that $L\left(M_{1}\right) \subset L\left(M_{2}\right)$, cf. Example 7.4.)
Theorem 3. Again, keep the above notations and assume that the common KillingCartan type of $G_{1}$ and $G_{2}$ is one of the following: $A_{n}, D_{2 n+1}(n>1)$ or $E_{6}$ and that the subgroups $\Gamma_{1}$ and $\Gamma_{2}$ are arithmetic. Assume in addition that $K_{\Gamma_{i}} \neq \mathbb{Q}$ for at least one $i \in\{1,2\}$. Then either $\mathbb{Q} \cdot L\left(M_{1}\right)=\mathbb{Q} \cdot L\left(M_{2}\right)$, hence $\mathscr{F}_{1}=\mathscr{F}_{2}$ (although $M_{1}$ and $M_{2}$ may not be commensurable), or conditions $\left(T_{i}\right)$ and $\left(N_{i}\right)$ hold for at least one $i \in\{1,2\}$.

These results can be used in various geometric situations. To illustrate the scope of possible applications, we will now give explicit statements for real hyperbolic manifolds (similar results are available for complex and quaternionic hyperbolic manifolds).

Corollary 1. Let $M_{i}(i=1,2)$ be the quotient of the real hyperbolic space $\mathbb{H}^{d_{i}}$ with $d_{i} \neq$ 3 by a torsion-free Zariski-dense discrete subgroup $\Gamma_{i}$ of $G_{i}(\mathbb{R})$ where $G_{i}=\operatorname{PSO}\left(d_{i}, 1\right)$.
(i) If $d_{1}>d_{2}$ then conditions $\left(T_{1}\right)$ and $\left(N_{1}\right)$ hold.
(ii) If $d_{1}=d_{2}$ but $K_{\Gamma_{1}} \not \subset K_{\Gamma_{2}}$ then again conditions $\left(T_{1}\right)$ and $\left(N_{1}\right)$ hold.

Thus, unless $d_{1}=d_{2}$ and $K_{\Gamma_{1}}=K_{\Gamma_{2}}$, conditions $\left(T_{i}\right)$ and $\left(N_{i}\right)$ hold for at least one $i \in\{1,2\}$.

Assume now that $d_{1}=d_{2}=: d$ and the subgroups $\Gamma_{1}$ and $\Gamma_{2}$ are arithmetic.
(iii) If $d$ is either even or is congruent to $3(\bmod 4)$, then either $M_{1}$ and $M_{2}$ are commensurable, hence length-commensurable and $\mathscr{F}_{1}=\mathscr{F}_{2}$, or $\left(T_{i}\right)$ and $\left(N_{i}\right)$ hold for at least one $i \in\{1,2\}$.
(iv) If $d \equiv 1(\bmod 4)$ and in addition $K_{\Gamma_{i}} \neq \mathbb{Q}$ for at least one $i \in\{1,2\}$ then either $M_{1}$ and $M_{2}$ are length-commensurable (although not necessarily commensurable), or conditions $\left(T_{i}\right)$ and $\left(N_{i}\right)$ hold for at least one $i \in\{1,2\}$.
The results of [5] enable us to consider the situation where one of the groups is of type $B_{n}$ and the other is of type $C_{n}$.

Theorem 4. Notations as above, assume that $G_{1}$ is of type $B_{n}$ and $G_{2}$ is of type $C_{n}$ for some $n \geqslant 3$ and the subgroups $\Gamma_{1}$ and $\Gamma_{2}$ are arithmetic. Then either $\left(T_{i}\right)$ and $\left(N_{i}\right)$ hold for at least one $i \in\{1,2\}$, or

$$
\mathbb{Q} \cdot L\left(M_{2}\right)=\lambda \cdot \mathbb{Q} \cdot L\left(M_{1}\right) \text { where } \lambda=\sqrt{\frac{2 n+2}{2 n-1}} .
$$

The following interesting result holds for all types.
Theorem 5. For $i=1,2$, let $M_{i}=\mathfrak{X}_{\Gamma_{i}}$ be an arithmetically defined locally symmetric space, and assume that $w_{1}=w_{2}$. If $M_{2}$ is compact and $M_{1}$ is not, then conditions ( $T_{1}$ ) and ( $N_{1}$ ) hold.

Finally, we have the following statement which shows that the notion of "similarity" (or more precisely, "length-similarity") for arithmetically defined locally symmetric spaces is redundant.

Corollary 2. Let $M_{i}=\mathfrak{X}_{\Gamma_{i}}$ for $i=1,2$ be arithmetically defined locally symmetric spaces. Assume that there exists $\lambda \in \mathbb{R}_{>0}$ such that

$$
\mathbb{Q} \cdot L\left(M_{1}\right)=\lambda \cdot \mathbb{Q} \cdot L\left(M_{2}\right) .
$$

Then
(i) if $G_{1}$ and $G_{2}$ are of the same type which is different from $A_{n}, D_{2 n+1}(n>1)$ and $E_{6}$, then $M_{1}$ and $M_{2}$ are commensurable, hence length-commensurable;
(ii) if $G_{1}$ and $G_{2}$ are of the same type which is one of the following: $A_{n}, D_{2 n+1}(n>$

1) or $E_{6}$ then, provided that $K_{\Gamma_{i}} \neq \mathbb{Q}$ for at least one $i \in\{1,2\}$, the spaces $M_{1}$ and $M_{2}$ are length-commensurable (although not necessarily commensurable).
(See Corollary 7.11 for a more detailed statement.)
While the geometric results in [13] were derived from an analysis of the relationship between Zariski-dense subgroups of semi-simple algebraic groups called weak commensurability, the results described above require a more general and technical version of this notion which we call weak containment. We recall that given two semi-simple groups $G_{1}$ and $G_{2}$ over a field $F$ and Zariski-dense subgroups $\Gamma_{i} \subset G_{i}(F)$ for $i=1,2$, two semi-simple elements $\gamma_{i} \in \Gamma_{i}$ are weakly commensurable if there exist maximal $F$-tori $T_{i}$ of $G_{i}$ such that $\gamma_{i} \in T_{i}(F)$, and for some characters $\chi_{i}$ of $T_{i}$ (defined over an algebraic closure $\bar{F}$ of $F$ ), we have

$$
\chi_{1}\left(\gamma_{1}\right)=\chi_{2}\left(\gamma_{2}\right) \neq 1
$$

Furthermore, $\Gamma_{1}$ and $\Gamma_{2}$ are weakly commensurable if every semi-simple element $\gamma_{1} \in \Gamma_{1}$ of infinite order is weakly commensurable to some semi-simple element $\gamma_{2} \in \Gamma_{2}$ of infinite order, and vice versa. The following definition provides a generalization of the notion of weak commensurability which is adequate for our purposes.
Definition 1. Notations as above, semi-simple elements $\gamma_{1}^{(1)}, \ldots, \gamma_{m_{1}}^{(1)} \in \Gamma_{1}$ are weakly contained in $\Gamma_{2}$ if there are semi-simple elements $\gamma_{1}^{(2)}, \ldots, \gamma_{m_{2}}^{(2)} \in \Gamma_{2}$ such that

$$
\chi_{1}^{(1)}\left(\gamma_{1}^{(1)}\right) \cdots \chi_{m_{1}}^{(1)}\left(\gamma_{m_{1}}^{(1)}\right)=\chi_{1}^{(2)}\left(\gamma_{1}^{(2)}\right) \cdots \chi_{m_{2}}^{(2)}\left(\gamma_{m_{2}}^{(2)}\right) \neq 1 .
$$

for some maximal $F$-tori $T_{k}^{(j)}$ of $G_{j}$ containing $\gamma_{k}^{(j)}$ and some characters $\chi_{k}^{(j)}$ of $T_{k}^{(j)}$ for $j \in\{1,2\}$ and $k \leqslant m_{j}$.
(It is easy to see that this property is independent of the choice of the maximal tori containing the elements in question.)

We also need the following.
Definition 2. (a) Let $T_{1}, \ldots, T_{m}$ be a finite collection of algebraic tori defined over a field $K$, and for each $i \leqslant m$, let $\gamma_{i} \in T_{i}(K)$. The elements $\gamma_{1}, \ldots, \gamma_{m}$ are called multiplicatively independent if a relation of the form

$$
\chi_{1}\left(\gamma_{1}\right) \cdots \chi_{m}\left(\gamma_{m}\right)=1
$$

where $\chi_{j} \in X\left(T_{j}\right)$, implies that

$$
\chi_{1}\left(\gamma_{1}\right)=\cdots=\chi_{m}\left(\gamma_{m}\right)=1
$$

(b) Let $G$ be a semi-simple algebraic $F$-group. Semi-simple elements $\gamma_{1}, \ldots, \gamma_{m} \in$ $G(F)$ are called multiplicatively independent if for some (equivalently, any) choice of maximal $F$-tori $T_{i}$ of $G$ such that $\gamma_{i} \in T_{i}(F)$ for $i \leqslant m$, these elements are multiplicatively independent in the sense of part (a).

We are now in a position to give a definition that plays the central role in the paper. Definition 3. We say that $\Gamma_{1}$ and $\Gamma_{2}$ as above satisfy property $\left(C_{i}\right)$, where $i=1$ or 2, if for any $m \geqslant 1$ there exist semi-simple elements $\gamma_{1}, \ldots, \gamma_{m} \in \Gamma_{i}$ of infinite order that are multiplicatively independent and are not weakly contained in $\Gamma_{3-i}$.

Our main effort is focused on developing a series of conditions that guarantee the fact that $\Gamma_{1}$ and $\Gamma_{2}$ satisfies $\left(C_{i}\right)$ for at least one $i \in\{1,2\}$ (in fact, typically we are able to pin down the $i$ ). Before formulating a sample result, we would like to note that the notion of the trace subfield (field of definition) $K_{\Gamma_{i}} \subset F$ makes sense for any field $F$ and not only for $F=\mathbb{R}$.
Theorem 4.2. Assume that $\Gamma_{1}$ and $\Gamma_{2}$ are finitely generated.
(i) If $w_{1}>w_{2}$ then condition $\left(C_{1}\right)$ holds;
(ii) If $w_{1}=w_{2}$ but $K_{\Gamma_{1}} \not \subset K_{\Gamma_{2}}$ then again ( $C_{1}$ ) holds.

Thus, unless $w_{1}=w_{2}$ and $K_{\Gamma_{1}}=K_{\Gamma_{2}}$, condition $\left(C_{i}\right)$ holds for at least one $i \in\{1,2\}$.
We prove much more precise results in the case where the $\Gamma_{i}$ are arithmetic. The statements however are somewhat technical, and we refer the reader to $\$ 50$ for their precise formulations.

The reader may have already noticed similarities in the statements of Theorem 1 and Theorem 4.2. The same similarities exist also between the "geometric" Theorems 2-4 and the corresponding "algebraic" results in \$55. The precise connection between "algebra" and "geometry" is given by Proposition 7.1] which has the following consequence (Corollary 7.3):
If $\mathfrak{X}_{\Gamma_{1}}$ and $\mathfrak{X}_{\Gamma_{2}}$ are locally symmetric spaces as above with finitely generated fundamental groups $\Gamma_{1}$ and $\Gamma_{2}$, then the fact that these groups satisfy property $\left(C_{i}\right)$ for some $i \in\{1,2\}$
implies that the locally symmetric spaces satisfy conditions $\left(T_{i}\right)$ and $\left(N_{i}\right)$ for the same $i$.

It should be noted that the proof of Proposition 7.1 assumes the truth of Schanuel's conjecture, and in fact it is the only place in the paper where the latter is used. In conjunction with the results of 95 this facts provides a series of rather restrictive conditions on the arithmetic groups $\Gamma_{1}$ and $\Gamma_{2}$ in case $\left(T_{i}\right)$ fails for both $i=1$ and 2 . Eventually, these condition enable us to prove that if $G_{1}$ and $G_{2}$ are of the same type which is different from $A_{n}, D_{2 n+1}(n>1)$ or $E_{6}$ then $G_{1} \simeq G_{2}$ over $K:=K_{\Gamma_{1}}=K_{\Gamma_{2}}$ and hence the subgroups $\Gamma_{1}$ and $\Gamma_{2}$ are commensurable in the appropriate sense (viz., up to an isomorphism between $G_{1}$ and $G_{2}$ ), yielding the commensurability of the locally symmetric spaces $\mathfrak{X}_{\Gamma_{1}}$ and $\mathfrak{X}_{\Gamma_{2}}$ (cf. Theorem 2). If $G_{1}$ and $G_{2}$ are of the same type which is one of the following $A_{n}, D_{2 n+1}(n>1)$ or $E_{6}$, then $G_{1}$ and $G_{2}$ may not be $K$-isomorphic, but using the results from [13], $\S 9$, and [14], we show that (under some minor restrictions) these groups necessarily have equivalent systems of maximal $K$-tori (see $\sqrt{6}$ for the precise definition) making the corresponding locally symmetric spaces $\mathfrak{X}_{\Gamma_{1}}$ and $\mathfrak{X}_{\Gamma_{2}}$ length-commensurable, and thereby proving Theorem 3. To prove Theorem 4, we use the results of [5] that describe when two absolutely almost simple $K$-groups, one of type $B_{n}$ and the other of type $C_{n}(n \geqslant 3)$, have the same isomorphism classes of maximal $K$-tori.

Notations. For a field $K, K_{\text {sep }}$ will denote a separable closure. Given a (finitely generated) field $K$ of characteristic zero, we let $V^{K}$ denote the set of (equivalence classes) of nontrivial valuations $v$ of $K$ with locally compact completion $K_{v}$. If $v \in V^{K}$ is nonarchimedean, then $K_{v}$ is a finite extension of the $p$-adic field $\mathbb{Q}_{p}$ for some $p$; in the sequel this prime $p$ will be denoted by $p_{v}$. Given a subset $V$ of $V^{K}$ consisting of nonarchimedean valuations, we set $\Pi_{V}=\left\{p_{v} \mid v \in V\right\}$.
Acknowledgements. We thank Skip Garibaldi for proving in 44 Theorem 5.4 which, in particular, enabled us to include type $D_{4}$ in Theorem 5.3. We also thank Sai-Kee Yeung for a discussion of his paper [20]. Both authors were partially supported by the NSF (grants DMS-1001748 and DMS-0965758) and the Humboldt Foundation. During the preparation of this paper, the second-named author was visiting the Mathematics Department of the University of Michigan as a Gehring Professor; the hospitality and generous support of this institution are thankfully acknowledged.

## 2. Weak containment

The goal of this section is to derive several consequences of the relation of weak containment (see Definition 1 of the Introduction) that will be needed later. We begin with some definitions and results for algebraic tori. Given a torus $T$ defined over a field $K$, we let $K_{T}$ denote its (minimal) splitting field over $K$ (contained in a fixed algebraic closure $\bar{K}$ of $K$ ). The following definition goes back to 9$]$.

Definition 4. A $K$-torus $T$ is called $K$-irreducible (or, irreducible over $K$ ) if it does not contain any proper $K$-subtori.

Recall that $T$ is $K$-irreducible if and only if $X(T) \otimes_{\mathbb{Z}} \mathbb{Q}$ is an irreducible $\operatorname{Gal}\left(K_{T} / K\right)$ module, cf. 9], Proposition 1. Now, let $G$ be an absolutely almost simple algebraic $K$-group. For a maximal torus $T$ of $G$, we let $\Phi=\Phi(G, T)$ denote the corresponding root system, and let $\operatorname{Aut}(\Phi)$ be the automorphism group of $\Phi$. As usual, the Weyl group $W(\Phi) \subset \operatorname{Aut}(\Phi)$ will be identified with the Weyl group $W(G, T)$ of $G$ relative to $T$. If $T$ is defined over a field extension $L$ of $K$, and $L_{T}$ is the splitting field of $T$ over $L$ in an algebraic closure of the latter, then there is a natural injective homomorphism

$$
\theta_{T}: \operatorname{Gal}\left(L_{T} / L\right) \rightarrow \operatorname{Aut}(\Phi)
$$

Since $W(\Phi)$ acts absolutely irreducibly on $X(T) \otimes_{\mathbb{Z}} \mathbb{Q}$, we conclude that a maximal $L$-torus $T$ of $G$ such that $\theta_{T}\left(\operatorname{Gal}\left(L_{T} / L\right)\right) \supset W(G, T)$ is automatically $L$-irreducible. (We also recall for the convenience of further reference that if $G$ is of inner type over $L$ then $\theta_{T}\left(\operatorname{Gal}\left(L_{T} / L\right)\right) \subset W(G, T)$, cf. [13], Lemma 4.1.)
Definition 5. Let $T_{1}, \ldots, T_{m}$ be $K$-tori. We say that these tori are independent (over $K)$ if their splitting fields $K_{T_{1}}, \ldots, K_{T_{m}}$ are linearly disjoint over $K$, i.e. the natural map

$$
K_{T_{1}} \otimes_{K} \cdots \otimes_{K} K_{T_{m}} \longrightarrow K_{T_{1}} \cdots K_{T_{m}}
$$

is an isomorphism.
Lemma 2.1. Let $T_{1}, \ldots, T_{m}$ be $K$-tori, and for $i \leqslant m$, let $\gamma_{i} \in T_{i}(K)$ be an element of infinite order. Assume that $T_{1}, \ldots, T_{m}$ are independent, irreducible and nonsplit over some extension $L$ of $K$. Then the elements $\gamma_{1}, \ldots, \gamma_{m}$ are multiplicatively independent (see Definition 2 in \$1).

Proof. Suppose there exist characters $\chi_{i} \in X\left(T_{i}\right)$ such that

$$
\chi_{1}\left(\gamma_{1}\right) \cdots \chi_{m}\left(\gamma_{m}\right)=1
$$

Since $\chi_{i}\left(\gamma_{i}\right) \in L_{T_{i}}^{\times}$and the tori $T_{1}, \ldots, T_{m}$ are independent over $L$, it follows that actually $\chi_{i}\left(\gamma_{i}\right) \in L^{\times}$for all $i \leqslant m$. Then for any $\sigma \in \operatorname{Gal}\left(L_{T_{i}} / L\right)$ we have

$$
\begin{equation*}
\left(\sigma \chi_{i}-\chi_{i}\right)\left(\gamma_{i}\right)=1 \tag{1}
\end{equation*}
$$

Being a $L$-rational element of infinite order in an $L$-irreducible torus $T_{i}$, the element $\gamma_{i}$ generates a Zariski-dense subgroup of the latter, so (11) implies that $\sigma \chi_{i}=\chi_{i}$. But $X\left(T_{i}\right)$ does not have nonzero $\operatorname{Gal}\left(L_{T_{i}} / L\right)$-fixed elements. Thus, $\chi_{i}=0$ and $\chi_{i}\left(\gamma_{i}\right)=1$.

The following lemma is crucial for unscrambling relations of weak containment.
Lemma 2.2. Let $T_{1}^{(1)}, \ldots, T_{m_{1}}^{(1)}$ and $T_{1}^{(2)}, \ldots, T_{m_{2}}^{(2)}$ be two finite families of algebraic $K$-tori, and suppose we are given a relation of the form

$$
\begin{equation*}
\chi_{1}^{(1)}\left(\gamma_{1}^{(1)}\right) \cdots \chi_{m_{1}}^{(1)}\left(\gamma_{m_{1}}^{(1)}\right)=\chi_{1}^{(2)}\left(\gamma_{1}^{(2)}\right) \cdots \chi_{m_{2}}^{(2)}\left(\gamma_{m_{2}}^{(2)}\right), \tag{2}
\end{equation*}
$$

where $\gamma_{i}^{(s)} \in T_{i}^{(s)}(K)$ and $\chi_{i}^{(s)} \in X\left(T_{i}^{(s)}\right)$. Assume that $T_{1}^{(1)}, \ldots, T_{m_{1}}^{(1)}$ are independent, irreducible and nonsplit over $K$. Then for every $i \leqslant m_{1}$ such that the corresponding character $\chi_{i}^{(1)}$ in (2) is nontrivial, there exists an integer $d_{i}>0$ with the following property:

For any $\delta_{i}^{(1)} \in d_{i} X\left(T_{i}^{(1)}\right)$ there are characters $\delta_{j}^{(2)} \in X\left(T_{j}^{(2)}\right)$ for $j \leqslant m_{2}$ for which

$$
\begin{equation*}
\delta_{i}^{(1)}\left(\gamma_{i}^{(1)}\right)=\delta_{1}^{(2)}\left(\gamma_{1}^{(2)}\right) \cdots \delta_{m_{2}}^{(2)}\left(\gamma_{m_{2}}^{(2)}\right) \tag{3}
\end{equation*}
$$

In addition, if $\gamma_{i}^{(1)}$ has infinite order and $\delta_{i}^{(1)} \neq 0$ then the common value in (3) is $\neq 1$.
Proof. As the tori $T_{1}^{(1)}, \ldots, T_{m_{1}}^{(1)}$ are independent over $K$, we have the natural isomorphism

$$
\begin{equation*}
\operatorname{Gal}\left(K_{T_{1}^{(1)}} \cdots K_{T_{m_{1}}^{(1)}} / K\right) \simeq \operatorname{Gal}\left(K_{T_{1}^{(1)}} / K\right) \times \cdots \times \operatorname{Gal}\left(K_{T_{m_{1}}^{(1)}} / K\right) \tag{4}
\end{equation*}
$$

Since $T_{i}^{(1)}$ is $K$-irreducible and nonsplit, $X\left(T_{i}^{(1)}\right)$ does not contain any nontrivial $\operatorname{Gal}\left(K_{T_{i}^{(1)}} / K\right)$-fixed elements. So, it follows from (4) that there exists $\sigma \in \operatorname{Gal}(\bar{K} / K)$ such that $\sigma \chi_{i}^{(1)} \neq \chi_{i}^{(1)}$ but $\sigma \chi_{j}^{(1)}=\chi_{j}^{(1)}$ for $j \neq i$. Applying $\sigma-1$ to (2), we obtain

$$
\begin{equation*}
\mu_{i}^{(1)}\left(\gamma_{i}^{(1)}\right)=\mu_{1}^{(2)}\left(\gamma_{1}^{(2)}\right) \cdots \mu_{m_{2}}^{(2)}\left(\gamma_{m_{2}}^{(2)}\right) \tag{5}
\end{equation*}
$$

where $\mu_{j}^{(s)}=\sigma \chi_{j}^{(s)}-\chi_{j}^{(s)}$, noting that $\mu_{i}^{(1)} \neq 0$. Again, since $T_{i}^{(1)}$ is $K$-irreducible and nonsplit, the $\operatorname{Gal}(\bar{K} / K)$-submodule of $X\left(T_{i}^{(1)}\right)$ generated by $\mu_{i}^{(1)}$ has finite index, hence it contains $d_{i} X\left(T_{i}^{(1)}\right)$ for some integer $d_{i}>0$. Then any $\delta_{i}^{(1)} \in d_{i} X\left(T_{i}^{(1)}\right)$ can be written as

$$
\delta_{i}^{(1)}=\sum n_{\sigma} \sigma\left(\mu_{i}^{(1)}\right) \text { for some } \sigma \in \operatorname{Gal}(\bar{K} / K) \text { and } n_{\sigma} \in \mathbb{Z}
$$

So, using (5) we obtain that

$$
\delta_{i}^{(1)}\left(\gamma_{i}^{(1)}\right)=\delta_{1}^{(2)}\left(\gamma_{1}^{(2)}\right) \cdots \delta_{m_{2}}^{(2)}\left(\gamma_{m_{2}}^{(2)}\right)
$$

with $\delta_{j}^{(2)}=\sum n_{\sigma} \sigma\left(\mu_{j}^{(2)}\right)$ for $j \leqslant m_{2}$. Finally, if $\gamma_{i}^{(1)}$ is of infinite order then it generates a Zariski-dense subgroup of the $K$-irreducible torus $T_{i}^{(1)}$, and therefore $\delta_{i}^{(1)}\left(\gamma_{i}^{(1)}\right) \neq 1$ for any nonzero $\delta_{i}^{(1)} \in X\left(T_{i}^{(1)}\right)$.

The following theorem is an adaptation of a part of the Isogeny Theorem (Theorem 4.2 ) of [13] suitable for our purposes.

Theorem 2.3. $\operatorname{Let} T_{1}^{(1)}, \ldots, T_{m_{1}}^{(1)}$ and $T_{1}^{(2)}, \ldots, T_{m_{2}}^{(2)}$ be two finite families of algebraic $K$-tori, and suppose we are given a relation of the form

$$
\begin{equation*}
\chi_{1}^{(1)}\left(\gamma_{1}^{(1)}\right) \cdots \chi_{m_{1}}^{(1)}\left(\gamma_{m_{1}}^{(1)}\right)=\chi_{1}^{(2)}\left(\gamma_{1}^{(2)}\right) \cdots \chi_{m_{2}}^{(2)}\left(\gamma_{m_{2}}^{(2)}\right) \tag{6}
\end{equation*}
$$

where $\gamma_{i}^{(s)} \in T_{i}^{(s)}(K)$ and $\chi_{i}^{(s)} \in X\left(T_{i}^{(s)}\right)$. Assume that the tori $T_{1}^{(1)}, \ldots, T_{m_{1}}^{(1)}$ are independent, irreducible and nonsplit over $K$, and that the elements $\gamma_{1}^{(1)}, \ldots, \gamma_{m_{1}}^{(1)}$ all have infinite order. Then for each $i \leqslant m_{1}$ such that the corresponding character $\chi_{i}^{(1)}$ in (6) is nontrivial, there exists a surjective $K$-homomorphism $T_{j}^{(2)} \rightarrow T_{i}^{(1)}$ for some $j \leqslant m_{2}$, hence, in particular, $K_{T_{i}^{(1)}} \subset K_{T_{j}^{(2)}}$. Moreover, if all the tori are of the same dimension, the above homomorphism is an isogeny and $K_{T_{i}^{(1)}}=K_{T_{j}^{(2)}}$.

Proof. Fix $i \leqslant m_{1}$ such that $\chi_{i}^{(1)} \neq 0$. Applying Lemma 2.2, we see that there is a relation of the form

$$
\delta_{i}^{(1)}\left(\gamma_{i}^{(1)}\right)=\delta_{1}^{(2)}\left(\gamma_{1}^{(2)}\right) \cdots \delta_{m_{2}}^{(2)}\left(\gamma_{m_{2}}^{(2)}\right)
$$

with $\delta_{i}^{(1)} \in X\left(T_{i}^{(1)}\right), \delta_{i}^{(1)} \neq 0$, and $\delta_{j}^{(2)} \in X\left(T_{j}^{(2)}\right)$ for $j \leqslant m_{2}$. To simplify our notation, we set

$$
T^{(1)}=T_{i}^{(1)}, \quad \gamma^{(1)}=\gamma_{i}^{(1)}, \quad \delta^{(1)}=\delta_{i}^{(1)}
$$

and

$$
T^{(2)}=T_{1}^{(2)} \times \cdots \times T_{m_{2}}^{(2)}, \quad \gamma^{(2)}=\left(\gamma_{1}^{(2)}, \ldots, \gamma_{m_{2}}^{(2)}\right), \quad \delta^{(2)}=\left(\delta_{1}^{(2)}, \ldots, \delta_{m_{2}}^{(2)}\right) .
$$

Then

$$
\delta^{(1)}\left(\gamma^{(1)}\right)=\delta^{(2)}\left(\gamma^{(2)}\right)=: \lambda .
$$

First, we will show that the Galois conjugates $\sigma(\lambda)$ for $\sigma \in \operatorname{Gal}\left(K_{T^{(1)}} / K\right)$ generate $K_{T^{(1)}}$ over $K$. Indeed, suppose $\tau \in \operatorname{Gal}\left(K_{T^{(1)}} / K\right)$ fixes all the $\sigma(\lambda)^{\prime}$ 's. Then for any $\sigma \in \operatorname{Gal}\left(K_{T^{(1)}} / K\right)$ we have

$$
\left(\tau \sigma\left(\delta^{(1)}\right)\right)\left(\gamma^{(1)}\right)=\tau(\sigma(\lambda))=\sigma(\lambda)=\left(\sigma\left(\delta^{(1)}\right)\right)\left(\gamma^{(1)}\right)
$$

Since $T^{(1)}$ is $K$-irreducible, the element $\gamma^{(1)} \in T^{(1)}(K)$, being of infinite order, generates a Zariski-dense subgroup of $T^{(1)}$. Hence, we conclude that $\tau\left(\sigma\left(\delta^{(1)}\right)\right)=\sigma\left(\delta^{(1)}\right)$ for all $\sigma \in \operatorname{Gal}\left(K_{T^{(1)}} / K\right)$. But the elements $\sigma\left(\delta^{(1)}\right)$ span $X\left(T^{(1)}\right) \otimes \mathbb{Z} \mathbb{Q}$ as $\mathbb{Q}$-vector space, so $\tau=\mathrm{id}$, and our claim follows.

Now, since all the elements $\sigma(\lambda)$ for $\sigma \in \operatorname{Gal}\left(K_{T^{(1)}} / K\right)$ belong to $K_{T^{(2)}}$, we obtain the inclusion $K_{T^{(1)}} \subset K_{T^{(2)}}$. So the restriction map

$$
\mathscr{G}:=\operatorname{Gal}\left(K_{T^{(2)}} / K\right) \longrightarrow \operatorname{Gal}\left(K_{T^{(1)}} / K\right)
$$

is a surjective homomorphism. In the rest of the proof, we will view $X\left(T^{(1)}\right)$ as a $\mathscr{G}$-module via this homomorphism. Define $\nu_{i}: \mathbb{Q}[\mathscr{G}] \rightarrow X\left(T^{(i)}\right) \otimes_{\mathbb{Z}} \mathbb{Q}$ by

$$
\sum_{\sigma \in \mathscr{G}} n_{\sigma} \sigma \mapsto \sum_{\sigma \in \mathscr{G}} n_{\sigma} \sigma\left(\delta^{(i)}\right) .
$$

We observe that $\delta^{(1)}\left(\gamma^{(1)}\right)=\delta^{(2)}\left(\gamma^{(2)}\right)$ implies that for any $a=\sum n_{\sigma} \sigma \in \mathbb{Z}[\mathscr{G}]$, we have

$$
\begin{equation*}
\nu_{2}(a)\left(\gamma^{(2)}\right)=\prod \sigma\left(\delta^{(2)}\left(\gamma^{(2)}\right)\right)^{n_{\sigma}}=\prod \sigma\left(\delta^{(1)}\left(\gamma^{(1)}\right)\right)^{n_{\sigma}}=\nu_{1}(a)\left(\gamma^{(1)}\right) . \tag{7}
\end{equation*}
$$

It is now easy to show that

## $\operatorname{Ker} \nu_{2} \subset \operatorname{Ker} \nu_{1}$.

Indeed, let $a \in \mathbb{Z}[\mathscr{G}]$ be such that $\nu_{2}(a)=0$. Then it follows from (7) that

$$
\nu_{2}(a)\left(\gamma^{(2)}\right)=1=\nu_{1}(a)\left(\gamma^{(1)}\right) .
$$

As $\gamma^{(1)}$ generates a Zariski-dense subgroup of $T^{(1)}$, we conclude that $\nu_{1}(a)=0$, and (8) follows.

Combining (8) with the fact that $\delta^{(1)}$ generates $X\left(T^{(1)}\right) \otimes_{\mathbb{Z}} \mathbb{Q}$ as a $\mathbb{Q}[\mathscr{G}]$-module, we get a surjective homomorphism

$$
\alpha: \operatorname{Im} \nu_{2} \longrightarrow \operatorname{Im} \nu_{1}=X\left(T^{(1)}\right) \otimes_{\mathbb{Z}} \mathbb{Q} .
$$

of $\mathbb{Q}[\mathscr{G}]$-modules. Because of semi-simplicity of $\mathbb{Q}[\mathscr{G}]$, there exists an injective $\mathbb{Z}[\mathscr{G}]$ module homomorphism $X\left(T^{(1)}\right) \rightarrow X\left(T^{(2)}\right)$, hence a surjective $K$-homomorphism $\theta: T^{(2)} \rightarrow T^{(1)}$. Pick $j \leqslant m_{2}$ so that the restriction $\left.\theta\right|_{T_{j}^{(2)}}$ is nontrivial. As $T^{(1)}$ is $K$-irreducible, we conclude that the resulting homomorphism $T_{j}^{(2)} \rightarrow T^{(1)}=T_{i}^{(1)}$ is surjective, hence the inclusion $K_{T_{i}^{(1)}} \subset K_{T_{j}^{(2)}}$. If $\operatorname{dim} T_{j}^{(2)}=\operatorname{dim} T_{i}^{(1)}$, then the above homomorphism is an isogeny implying that in fact $K_{T_{i}^{(1)}}=K_{T_{j}^{(2)}}$.

## 3. Existence of independent irreducible tori

In order to apply Theorem 2.3 in our analysis of the weak containment relation, we need to provide an adequate supply of regular semi-simple elements in a given finitely generated Zariski-dense subgroup whose centralizers yield arbitrarily large families of independent irreducible tori. Such elements are constructed in this section using a suitable generalization, along the lines indicated in [11], of the result established in [10] (see also [13], §3) guaranteeing the existence, in any Zariski-dense subgroup, of elements whose centralizers are irreducible tori.

Let $G$ be a connected semi-simple algebraic group defined over a field $K$, and let $T$ be a maximal torus of $G$ defined over a field extension $L$ of $K$. We will systematically use the notations introduced after Definition 4 in $\mathbb{2}$, particularly the natural homomorphism $\theta_{T}: \operatorname{Gal}\left(L_{T} / L\right) \rightarrow \operatorname{Aut}(\Phi(G, T))$. For the convenience of reference, we now quote Theorem 3.1 of [13].

Theorem 3.1. Let $G$ be a connected absolutely almost simple algebraic group defined over a finitely generated field $K$ of characteristic zero, and $L$ be a finitely generated field containing $K$. Let $r$ be the number of nontrivial conjugacy classes in the (absolute) Weyl group of $G$, and suppose we are given $r$ inequivalent nontrivial discrete valuations $v_{1}, \ldots, v_{r}$ of $K$ such that the completion $K_{v_{i}}$ is locally compact and contains $L$, and $G$ splits over $K_{v_{i}}$, for each $i \leqslant r$. Then there exist maximal $K_{v_{i}}$-tori $T\left(v_{i}\right)$ of $G$, one for each $i \leqslant r$, with the property that for any maximal $K$-torus $T$ of $G$ which is conjugate to $T\left(v_{i}\right)$ by an element of $G\left(K_{v_{i}}\right)$ for all $i \leqslant r$, we have

$$
\begin{equation*}
\theta_{T}\left(\operatorname{Gal}\left(L_{T} / L\right)\right) \supset W(G, T) \tag{9}
\end{equation*}
$$

The following corollary (see Corollary 3.2 in [13]) is derived from Theorem [3.1]using weak approximation property of the variety of maximal tori of $G$.

Corollary 3.2. Let $G, K$ and $L$ be as in Theorem [3.1, and let $V$ be a finite set of inequivalent nontrivial rank 1 valuations of $K$. Suppose that for each $v \in V$ we are given a maximal $K_{v}$-torus $T(v)$ of $G$. Then there exists a maximal $K$-torus $T$ of $G$ for which (9) holds and which is conjugate to $T(v)$ by an element of $G\left(K_{v}\right)$, for all $v \in V$.
(In Corollary 3.2 of [13] it was assumed that for each $v \in V$, the completion $K_{v}$ is locally compact. But as the Implicit Function Theorem holds over $K_{v}$ for any rank 1 valuation $v$ of $K$, the proof of Corollary 3.2 in [13] can be modified to prove the above more general result.)

We will now strengthen the above corollary to obtain arbitrarily large families of irreducible independent tori.

Theorem 3.3. Let $G$ be a connected absolutely almost simple algebraic group defined over a finitely generated field $K$ of characteristic zero, and $L$ be any finitely generated field extension of $K$ over which $G$ is of inner type. Furthermore, let $V$ be a finite set of inequivalent nontrivial rank 1 valuations of $K$ such that any $v \in V$ is either discrete or the corresponding completion $K_{v}$ is locally compact. Fix $m \geqslant 1$, and suppose that for each $v \in V$ we are given $m$ maximal $K_{v}$-tori $T_{1}(v), \ldots, T_{m}(v)$ of $G$. Then there exist maximal $K$-tori $T_{1}, \ldots, T_{m}$ of $G$ such that
(i) for each $j \leqslant m$, the torus $T_{j}$ satisfies

$$
\begin{equation*}
\theta_{T_{j}}\left(\operatorname{Gal}\left(L_{T_{j}} / L\right)\right) \supset W\left(G, T_{j}\right), \tag{10}
\end{equation*}
$$

in particular, $T_{j}$ is L-irreducible;
(ii) $T_{j}$ is conjugate to $T_{j}(v)$ by an element of $G\left(K_{v}\right)$ for all $v \in V$;
(iii) the tori $T_{1}, \ldots, T_{m}$ are independent over $L$.

Proof. We will induct on $m$. If $m=1$, then the existence of a maximal $K$-torus $T=T_{1}$ satisfying $(i)$ and $(i i)$ is established in Corollary 3.2, while condition $(i i i)$ is vacuous in this case. Now, let $m>1$ and assume that the maximal tori $T_{1}, \ldots, T_{m-1}$ satisfying conditions (i), (ii), and independent over $L$, have already been found. Let $L^{\prime}$ denote the compositum of the fields $L_{T_{1}}, \ldots, L_{T_{m-1}}$. Applying Corollary 3.2 with $L^{\prime}$ in place of $L$, we find a maximal $K$-torus $T_{m}$ which is conjugate to $T_{m}(v)$ by an element of $G\left(K_{v}\right)$ for all $v \in V$ and satisfies

$$
\begin{equation*}
\theta_{T_{m}}\left(\operatorname{Gal}\left(L_{T_{m}}^{\prime} / L^{\prime}\right)\right) \supset W\left(G, T_{m}\right) \tag{11}
\end{equation*}
$$

Then $T_{m}$ obviously satisfies conditions $(i)$ and $(i i)$. To see that $T_{1}, \ldots, T_{m}$ satisfy condition (iii), we observe that as the group $G$ is of inner type over $L$, according to [13], Lemma 4.1, we have

$$
\theta_{T_{j}}\left(\operatorname{Gal}\left(L_{T_{j}} / L\right)\right)=W\left(G, T_{j}\right) \text { for all } j \leqslant m .
$$

Since $L^{\prime}=L_{T_{1}} \cdots L_{T_{m-1}}$, it follows from (11) that

$$
\left[L_{T_{1}} \cdots L_{T_{m}}: L_{T_{1}} \cdots L_{T_{m-1}}\right]=\left|W\left(G, T_{m}\right)\right| .
$$

By induction hypothesis, $T_{1}, \ldots, T_{m-1}$ are independent over $L$, hence

$$
\left[L_{T_{1}} \cdots L_{T_{m-1}}: L\right]=\prod_{j=1}^{m-1}\left[L_{T_{j}}: L\right]=\prod_{j=1}^{m-1}\left|W\left(G, T_{j}\right)\right|
$$

Thus,

$$
\left[L_{T_{1}} \cdots L_{T_{m}}: L\right]=\prod_{j=1}^{m}\left|W\left(G, T_{j}\right)\right|=\prod_{j=1}^{m}\left[L_{T_{j}}: L\right],
$$

and therefore $T_{1}, \ldots, T_{m}$ are independent over $L$.

Next, we will establish a variant of Theorem 3.3 which asserts the existence of regular semi-simple elements in a given Zariski-dense subgroup whose centralizers possess properties $(i),(i i)$ and (iii) of the preceding theorem.
Theorem 3.4. Let $G, K$ and $L$ be as in Theorem 3.3 and $V$ be a finite set of inequivalent nontrivial discrete valuations of $K$ such that for every $v \in V$, the completion $K_{v}$ of $K$ is locally compact. Again, fix $m \geqslant 1$, and suppose that for each $v \in V$ we are given $m$ maximal $K_{v}$-tori $T_{1}(v), \ldots, T_{m}(v)$ of $G$. Let $\Gamma \subset G(K)$ be a finitely generated Zariski-dense subgroup such that the closure of the image of the diagonal map

$$
\Gamma \hookrightarrow \prod_{v \in V} G\left(K_{v}\right)
$$

is open. Then there exist regular semi-simple elements $\gamma_{1}, \ldots, \gamma_{m} \in \Gamma$ of infinite order such that the maximal $K$-tori $T_{j}=Z_{G}\left(\gamma_{j}\right)^{\circ}$ for $j \leqslant m$, satisfy
(i) for each $j \leqslant m$ we have

$$
\begin{equation*}
\theta_{T_{j}}\left(\operatorname{Gal}\left(L_{T_{j}} / L\right)\right) \supset W\left(G, T_{j}\right) \tag{12}
\end{equation*}
$$

(in particular, $T_{j}$ is L-irreducible, hence $\gamma_{j}$ generates a Zariski-dense subgroup of $T_{j}$ );
(ii) $T_{j}$ is conjugate to $T_{j}(v)$ by an element of $G\left(K_{v}\right)$ for all $v \in V$;
(iii) the tori $T_{1}, \ldots, T_{m}$ are independent over $L$.

Proof. We begin with the following lemma.
Lemma 3.5. Let $\mathcal{G}$ be a connected absolutely almost simple algebraic group over a field $\mathcal{K}$ of characteristic zero, $\Gamma$ be a Zariski-dense subgroup of $\mathcal{G}(\mathcal{K})$. Furthermore, let $\mathscr{V}$ be a finite set of nontrivial discrete valuations such that for each $v \in \mathscr{V}$, the completion $\mathcal{K}_{v}$ is locally compact, hence a finite extension of $\mathbb{Q}_{p_{v}}$ for some prime $p_{v}$. Assume that the closure of the image of the diagonal map

$$
\Gamma \longrightarrow \prod_{v \in \mathscr{V}} \mathcal{G}\left(\mathcal{K}_{v}\right)=: \mathcal{G}_{\mathscr{V}}
$$

is open in $\mathcal{G}_{\mathscr{V}}$. Let now $\mathscr{W}$ be another finite set of nontrivial discrete valuations of $\mathcal{K}$ such that for each $w \in \mathscr{W}$ we have $\mathcal{K}_{w}=\mathbb{Q}_{p_{w}}$ for the corresponding prime $p_{w}$ and that $\Gamma$ is a nondiscrete subgroup of $\mathcal{G}\left(\mathcal{K}_{w}\right)$ (which is automatically the case if $\Gamma$ is relatively compact in $\mathcal{G}\left(\mathcal{K}_{w}\right)$ ). If the primes $p_{w}$ for $w \in \mathscr{W}$ are pairwise distinct and none of them is contained in $\Pi_{\mathscr{V}}=\left\{p_{v} \mid v \in \mathscr{V}\right\}$, then the closure $\bar{\Gamma}^{(\mathscr{V} \cup \mathscr{W})}$ of the image of the diagonal map

$$
\Gamma \longrightarrow \prod_{v \in \mathscr{W} \cup \mathscr{W}} \mathcal{G}\left(\mathcal{K}_{v}\right)=: \mathcal{G}_{\mathscr{V} \cup \mathscr{W}}
$$

is also open.
Proof. Replacing $\Gamma$ with $\Gamma \cap \Omega$ for a suitable open subgroup $\Omega$ of $\mathcal{G}_{\mathscr{V}}$, we can assume that the closure $\bar{\Gamma}^{(V)}$ of $\Gamma$ in $\mathcal{G}_{\mathscr{V}}$ is of the form

$$
\bar{\Gamma}^{(\mathscr{V})}=\prod_{v \in \mathscr{V}} \mathcal{U}_{v}
$$

where $\mathcal{U}_{v}$ is an open pro- $p_{v}$ subgroup of $\mathcal{G}\left(\mathcal{K}_{v}\right)$. (We notice that for any open subgroup $\Omega \subset \mathcal{G}_{\mathscr{V}}$, the intersection $\Gamma \cap \Omega$ is still Zariski-dense in $G$ as its closure in $\mathcal{G}\left(\mathcal{K}_{v}\right)$ contains an open subgroup, for every $v \in \mathscr{V}$.) A standard argument (cf. [10], Lemma 2) shows that the closure $\bar{\Gamma}^{(w)}$ of $\Gamma$ in $\mathcal{G}\left(\mathcal{K}_{w}\right)$ is open for any $w \in \mathscr{W}$. Moreover, as above, we can assume, after replacing $\Gamma$ with a subgroup of finite index, that $\bar{\Gamma}^{(w)}$ is a pro- $p_{w}$ group. It is enough to prove that

$$
\begin{equation*}
\bar{\Gamma}^{(\mathscr{V} \cup \mathscr{W})}=\bar{\Gamma}^{(\mathscr{Y})} \times \prod_{w \in \mathscr{W}} \bar{\Gamma}^{(w)}=: \Theta . \tag{13}
\end{equation*}
$$

Since the primes $p_{w}, w \in \mathscr{W}$, are pairwise distinct and none of them is contained in $\Pi_{\mathscr{V}}$, we conclude that $\bar{\Gamma}^{(w)}$ is the unique Sylow $p_{w}$-subgroup of $\Theta$, for all $w \in \mathscr{W}$. As the projection $\bar{\Gamma}^{(\mathscr{V} \cup \mathscr{W})} \rightarrow \bar{\Gamma}^{(w)}$ is a surjective homomorphism of profinite groups, a Sylow pro- $p_{w}$ subgroup of $\bar{\Gamma}^{(\mathscr{V} \cup \mathscr{W})}$ must map onto $\bar{\Gamma}^{(w)}$. This implies that $\bar{\Gamma}^{(w)} \subset \bar{\Gamma}^{(\mathscr{H} \cup \mathscr{W})}$ for each $w \in \mathscr{W}$, and (13) follows.

Continuing the proof of Theorem 3.4, we fix a matrix realization of $G$ as a $K$-subgroup of $\mathrm{GL}_{n}$, and pick a finitely generated subring $R$ of $K$ such that $\Gamma \subset \mathrm{GL}_{n}(R)$. We will now argue by induction on $m$. Let $r$ be the number of nontrivial conjugacy classes in the (absolute) Weyl group of $G$. For $m=1$ the argument basically mimics the proof of Theorem 2 in [10]. More precisely, by Proposition 1 of [10], we can choose $r$ distinct primes $p_{1}, \ldots, p_{r} \notin \Pi_{V}$ such that for each $i \in\{1, \ldots, r\}$ there exists an embedding $\iota_{p_{i}}: L \hookrightarrow \mathbb{Q}_{p_{i}}$ such that $\iota_{p_{i}}(R) \subset \mathbb{Z}_{p_{i}}$ and $G$ splits over $\mathbb{Q}_{p_{i}}$. For a nontrivial discrete valuation $v$ of $K$ and a given maximal $K_{v}$-torus $T$ of $G$, we let $\mathscr{U}(T, v)$ denote the set of elements of the form $g t g^{-1}$, with $t \in T\left(K_{v}\right)$ regular and $g \in G\left(K_{v}\right)$. It is known that $\mathscr{U}(T, v)$ is a solid 1 open subset of $G\left(K_{v}\right)$ (cf. [13], Lemma 3.4). Let $v_{i}$ be pullback to $L$ of the $p_{i}$-adic valuation on $\mathbb{Q}_{p_{i}}$ under $\iota_{p_{i}}$ (so that $L_{v_{i}}=\mathbb{Q}_{p_{i}}$ ). Let $T\left(v_{1}\right), \ldots, T\left(v_{r}\right)$ be the tori given by Theorem 3.1, By our construction, for each $i \leqslant r$, the group $\Gamma$ is contained in $G\left(\mathbb{Z}_{p_{i}}\right)$, hence is relatively compact. Thus Lemma 3.5 applies, and since for any $v \in V \cup\left\{v_{1}, \ldots, v_{r}\right\}$, the group $G\left(K_{v}\right)$ contains a torsion-free open subgroup, it follows from Lemma 3.5 that there exists an element of infinite order

$$
\gamma_{1} \in \Gamma \bigcap\left(\prod_{v \in V} \mathscr{U}\left(T_{1}(v), v\right) \times \prod_{i \leqslant r} \mathscr{U}\left(T\left(v_{i}\right), v_{i}\right)\right),
$$

and this element is as required. For $m>1$, we proceed as in the proof of Theorem 3.3. Suppose that the elements $\gamma_{1}, \ldots, \gamma_{m-1}$ for which the corresponding $T_{1}, \ldots, T_{m-1}$ satisfy $(i)$ and (ii), and are independent over $L$, have already been found. Let $L^{\prime}$ denote the compositum of the fields $L_{T_{1}}, \ldots, L_{T_{m-1}}$. We then again use Proposition 1 of 10 ] to find $r$ distinct primes $p_{1}^{\prime}, \ldots, p_{r}^{\prime} \notin \Pi_{V}$ such that for each $i \leqslant r$, there exists an embedding $\iota_{p_{i}^{\prime}}^{\prime}: L^{\prime} \hookrightarrow \mathbb{Q}_{p_{i}^{\prime}}$ with the property $\iota_{p_{i}^{\prime}}^{\prime}(R) \subset \mathbb{Z}_{p_{i}^{\prime}}$. As $G$ splits over $L^{\prime}$, it splits over $\mathbb{Q}_{p_{i}^{\prime}}$. Let $v_{i}^{\prime}$ be the pullback of the $p_{i}^{\prime}$-adic valuation on $\mathbb{Q}_{p_{i}^{\prime}}$ under $\iota_{p_{i}^{\prime}}^{\prime}$ (and then

[^0]$L_{v_{i}^{\prime}}^{\prime}=\mathbb{Q}_{p_{i}^{\prime}}$. We use Theorem 3.1 to find, for each $i \leqslant r$, an $L_{v_{i}^{\prime}}^{\prime}$ torus $T^{\prime}\left(v_{i}^{\prime}\right)$ of $G$ such that for any maximal $K$-torus $T^{\prime}$ of $G$ which is conjugate to $T^{\prime}\left(v_{i}^{\prime}\right)$ by an element of $G\left(L_{v_{i}^{\prime}}^{\prime}\right)$ for all $i \leqslant r$, we have
$$
\theta_{T^{\prime}}\left(\operatorname{Gal}\left(L_{T^{\prime}}^{\prime} / L^{\prime}\right)\right) \supset W\left(G, T^{\prime}\right)
$$

As above, there exists an element of infinite order

$$
\gamma_{m} \in \Gamma \bigcap\left(\prod_{v \in V} \mathscr{U}\left(T_{m}(v), v\right) \times \prod_{i \leqslant r} \mathscr{U}\left(T^{\prime}\left(v_{i}^{\prime}\right), v_{i}^{\prime}\right)\right)
$$

Then $\gamma_{m}$ clearly satisfies $(i)$ and (ii), and the fact that $T_{1}, \ldots, T_{m}$ are independent over $L$ is established just as in the proof of Theorem 3.3,

## 4. Field of definition

Let $G_{1}$ and $G_{2}$ be connected absolutely simple algebraic groups of adjoint type defined over a field $F$ of characteristic zero. As before, we let $w_{i}$ denote the order of the (absolute) Weyl group of $G_{i}$ for $i=1,2$. Suppose that for each $i \in\{1,2\}$ we are given a finitely generated Zariski-dense subgroup $\Gamma_{i}$ of $G_{i}(F)$. Our goal in $\S \S 4[5$ is to develop a series of conditions which must hold in order to prevent the subgroups $\Gamma_{1}$ and $\Gamma_{r}$ from satisfying condition $\left(C_{i}\right)$ (see Definition 3 in §1) for at least one $i \in\{1,2\}$. Here is our first, rather straightforward, result in this direction.

Theorem 4.1. (i) If every regular semi-simple element $\gamma \in \Gamma_{1}$ of infinite order is weakly contained in $\Gamma_{2}$ then $\mathrm{rk} G_{1} \leqslant \operatorname{rk} G_{2}$ and $w_{1}$ divides $w_{2}$.
(ii) If $w_{1}>w_{2}$, then property $\left(C_{1}\right)$ holds.

Proof. ( $i$ ) We fix a finitely generated subfield $K$ of $F$ such that for $i=1$ and 2, the group $G_{i}$ is defined and of inner type over $K$ and $\Gamma_{i} \subset G_{i}(K)$. By Theorem 3.4, there exists a regular semi-simple element $\gamma \in \Gamma_{1}$ of infinite order such that for the corresponding torus $T=Z_{G_{1}}(\gamma)^{\circ}$ we have

$$
\theta_{T}\left(\operatorname{Gal}\left(K_{T} / K\right)\right) \supset W\left(G_{1}, T\right) ;
$$

we notice that since $G_{1}$ is of inner type over $K$, this inclusion is actually an equality, cf. Lemma 4.1 of [13]. The fact that $\gamma$ is weakly contained in $\Gamma_{2}$ means that one can find semi-simple elements $\gamma_{1}^{(2)}, \ldots, \gamma_{m_{2}}^{(2)} \in \Gamma_{2}$ so that for some characters $\chi \in X(T)$ and $\chi_{j}^{(2)} \in X\left(T_{j}^{(2)}\right)$, where $T_{j}^{(2)}$ is a maximal $K$-torus of $G_{2}$ containing $\gamma_{j}^{(2)}$, there is a relation of the form

$$
\chi(\gamma)=\chi_{1}^{(2)}\left(\gamma_{1}^{(2)}\right) \cdots \chi_{m_{2}}^{(2)}\left(\gamma_{m_{2}}^{(2)}\right) \neq 1
$$

Then it follows from Theorem [2.3 that for some $j \leqslant m_{2}$, there exists a surjective $K$-homomorphism $T_{j}^{(2)} \rightarrow T$. Then $\operatorname{rk} G_{1} \leqslant \operatorname{rk} G_{2}$ and there exists a surjective homomorphism $\operatorname{Gal}\left(K_{T_{j}^{(2)}} / K\right) \rightarrow \operatorname{Gal}\left(K_{T} / K\right)$. Since

$$
\theta_{T_{j}^{(2)}}\left(\operatorname{Gal}\left(K_{T_{j}^{(2)}} / K\right)\right) \subset W\left(G_{2}, T_{j}^{(2)}\right)
$$

(Lemma 4.1 of [13]), our assertion follows.
(ii) The argument here basically repeats the argument given above with minor modifications. Let $K$ be chosen as in the proof of $(i)$. To verify property $\left(C_{1}\right)$, we use Theorem 3.4 to find, for any given $m \geqslant 1$, regular semi-simple elements $\gamma_{1}, \ldots, \gamma_{m} \in \Gamma_{1}$ of infinite order such that for the corresponding maximal $K$-tori $T_{i}=Z_{G_{1}}\left(\gamma_{i}\right)^{\circ}$ of $G_{1}$ we have

$$
\theta_{T_{i}}\left(\operatorname{Gal}\left(K_{T_{i}} / K\right)\right) \supset W\left(G_{1}, T_{i}\right) \quad \text { for all } i \leqslant m,
$$

and the tori $T_{1}, \ldots, T_{m}$ are independent over $K$. Then the elements $\gamma_{1}, \ldots, \gamma_{m}$ are multiplicatively independent by Lemma [2.1, and we only need to show that they are not weakly contained in $\Gamma_{2}$ given that $w_{1}>w_{2}$. Otherwise, we would have a relation of the form

$$
\chi_{1}\left(\gamma_{1}\right) \cdots \chi_{m}\left(\gamma_{m}\right)=\chi_{1}^{(2)}\left(\gamma_{1}^{(2)}\right) \cdots \chi_{m_{2}}^{(2)}\left(\gamma_{m_{2}}^{(2)}\right) \neq 1
$$

with $\chi_{j} \in X\left(T_{j}\right)$ and the other objects as in the proof of $(i)$. Invoking again Theorem 2.3, we see that for some $i \leqslant m$ and $j \leqslant m_{2}$, there exists a surjective $K$-homomorphism $T_{j}^{(2)} \rightarrow T_{i}$. As above, this implies that $w_{1}$ divides $w_{2}$, contradicting the fact that by our assumption $w_{1}>w_{2}$.

Now, let $K_{i}=K_{\Gamma_{i}}$ denote the field of definition of $\Gamma_{i}$, i.e. the subfield of $F$ generated by the traces $\operatorname{Tr} \operatorname{Ad}_{G_{i}}(\gamma)$ for all $\gamma \in \Gamma_{i}$ (cf. [19]). Since $\Gamma_{i}$ is finitely generated, $\operatorname{Ad}_{G_{i}}\left(\Gamma_{i}\right)$ is contained in $\mathrm{GL}_{n_{i}}\left(F_{i}\right)$ for some finitely generated subfield $F_{i}$ of $F$. Then $K_{i}$ is a subfield of $F_{i}$, hence it is finitely generated. Since $G_{i}$ is adjoint, according to the results of Vinberg [19], it is defined over $K_{i}$ and $\Gamma_{i} \subset G_{i}\left(K_{i}\right)$.

The following theorem, announced in the introduction, is the main result of this section.

Theorem 4.2. (i) If $w_{1}>w_{2}$ then condition $\left(C_{1}\right)$ holds;
(ii) If $w_{1}=w_{2}$ but $K_{1} \not \subset K_{2}$ then again $\left(C_{1}\right)$ holds.

Thus, unless $w_{1}=w_{2}$ and $K_{1}=K_{2}$, condition $\left(C_{i}\right)$ holds for at least one $i \in\{1,2\}$.
Proof. Assertion (i) has already been established in Theorem 4.1, For $i=1,2$, as the group $G_{i}$ has been assumed to be of adjoint type, it is defined over $K_{i}$ and $\Gamma_{i} \subset G_{i}\left(K_{i}\right)$. Set $K=K_{1} K_{2}$, and pick a finite extension $L$ of $K$ so that $G_{i}$ splits over $L$ for both $i \in\{1,2\}$; clearly, $L$ is finitely generated. Fix a matrix realization of $G_{1}$ as a $K_{1}$ subgroup of $\mathrm{GL}_{n}$, and pick a finitely generated subring $R$ of $K_{1}$ so that $\Gamma \subset G_{1}(R)$. Since by our assumption $K_{1} \not \subset K_{2}$, we have $K_{2} \varsubsetneqq K \subset L$. So, using Proposition 5.1 of [13], we can find a prime $q$ such that there exists a pair of embeddings

$$
\iota^{(1)}, \iota^{(2)}: L \hookrightarrow \mathbb{Q}_{q}
$$

which have the same restrictions to $K_{2}$ but different restrictions to $K$, hence to $K_{1}$, and which satisfy the condition $\iota^{(j)}(R) \subset \mathbb{Z}_{q}$ for $j=1,2$. Let $v^{(j)}$ be the pullback to $K_{1}$ of the $q$-adic valuation of $\mathbb{Q}_{q}$ under $\left.\iota^{(j)}\right|_{K_{1}}$. The group $G_{1}\left(\left(K_{1}\right)_{v^{(j)}}\right)$ can be naturally identified with $G_{1}^{(j)}\left(\mathbb{Q}_{q}\right)$, where $G_{1}^{(j)}$ denotes the algebraic $\mathbb{Q}_{q}$-group obtained from the $K_{1}$-group $G_{1}$ by the extension of scalars $\left.\iota^{(j)}\right|_{K_{1}}: K_{1} \rightarrow \mathbb{Q}_{q}$, for $j=1,2$. Since $\iota^{(1)}$ and
$\iota^{(2)}$ have different restrictions to $K_{1}$, it follows from Proposition 5.2 of [13] that the closure of the image of $\Gamma_{1}$ under the diagonal embedding

$$
\begin{equation*}
\Gamma_{1} \longrightarrow G_{1}\left(\left(K_{1}\right)_{v^{(1)}}\right) \times G_{1}\left(\left(K_{1}\right)_{v^{(2)}}\right) \tag{14}
\end{equation*}
$$

is open. By our construction, $G_{1}$ splits over $\left(K_{1}\right)_{v^{(1)}}=\mathbb{Q}_{q}$ (recall that $\iota^{(1)}(L) \subset \mathbb{Q}_{q}$ and $G_{1}$ splits over $L$ ), so we can pick a $\left(K_{1}\right)_{v^{(1)}}$-split torus $T^{\left(v^{(1)}\right)}$ of $G_{1}$. Furthermore, by Theorem 6.21 of [7] there exists a maximal $\left(K_{1}\right)_{v^{(2)}}$-torus $T^{\left(v^{(2)}\right)}$ of $G_{1}$ which is anisotropic over $\left(K_{1}\right)_{v^{(2)}}$.

Set $V=\left\{v^{(1)}, v^{(2)}\right\}$. It follows from Theorem 3.4 that for any $m \geqslant 1$ there exist regular semi-simple elements $\gamma_{1}, \ldots, \gamma_{m} \in \Gamma_{1}$ of infinite order such that the maximal tori $T_{i}=Z_{G_{1}}\left(\gamma_{i}\right)^{\circ}$ for $i \leqslant m$ are independent over $L$ and satisfy the following conditions for all $i \leqslant m$ :

- $\theta_{T_{i}}\left(\operatorname{Gal}\left(L_{T_{i}} / L\right)\right) \supset W\left(G_{1}, T_{i}\right)$;
- $T_{i}$ is conjugate to $T^{(v)}$ for $v \in V$.

We claim that these elements are allow us to check the property $\left(C_{1}\right)$. Indeed, it follows from Lemma 2.1 that these elements are multiplicatively independent, and we only need to show that they are not weekly contained in $\Gamma_{2}$. Assume the contrary. As $w_{1}=w_{2}$, we conclude that rk $G_{1}=\mathrm{rk} G_{2}$, and there exists a maximal $K_{2}$-torus $T^{\prime}$ of $G_{2}$ that admits an $L$-isogeny $\kappa: T^{\prime} \rightarrow T$ onto $T=T_{i}$ for some $i \leqslant m$ (see the proof of Theorem 4.1(ii)), and then

$$
L_{T}=L_{T^{\prime}}=: \mathscr{F}
$$

Observe that

$$
\begin{equation*}
\mathscr{F}=L \cdot K_{1 T}=L \cdot K_{2 T^{\prime}} \tag{15}
\end{equation*}
$$

Fix some extensions

$$
\tilde{\iota}^{(1)}, \tilde{\iota}^{(2)}: \mathscr{F} \rightarrow \overline{\mathbb{Q}}_{q} \quad\left(\overline{\mathbb{Q}}_{q} \text { is the algebraic closure of } \mathbb{Q}_{q}\right)
$$

of $\iota^{(1)}$ and $\iota^{(2)}$ respectively. Let $u$ be the pullback to $K_{2}$ of the $q$-adic valuation of $\mathbb{Q}_{q}$ under $\left.\iota^{(1)}\right|_{K_{2}}=\left.\iota^{(2)}\right|_{K_{2}}$. Furthermore, let $\tilde{v}^{(1)}, \tilde{v}^{(2)}$ (resp., $\tilde{u}^{(1)}, \tilde{u}^{(2)}$ ) be the valuations of $K_{1 T}$ (resp., of $K_{2 T^{\prime}}$ ) obtained as pullbacks of the valuation of $\overline{\mathbb{Q}}_{q}$ under appropriate restrictions of $\tilde{\iota}^{(1)}$ and $\tilde{\iota}^{(2)}$. Then $\tilde{u}^{(1)}$ and $\tilde{u}^{(2)}$ are two extensions of $u$ to the Galois extension $K_{2 T^{\prime}} / K_{2}$, and therefore

$$
\begin{equation*}
\left[\left(K_{2 T^{\prime}}\right)_{\tilde{u}^{(1)}}:\left(K_{2}\right)_{u}\right]=\left[\left(K_{2 T^{\prime}}\right)_{\tilde{u}^{(2)}}:\left(K_{2}\right)_{u}\right] \tag{16}
\end{equation*}
$$

On the other hand, since ${ }_{\iota}{ }^{(j)}(L) \subset \mathbb{Q}_{q}$ for $j=1$, 2 , we have

$$
\left(K_{2}\right)_{u}=\mathbb{Q}_{q} \quad \text { and } \quad\left(K_{1}\right)_{v^{(1)}}=\mathbb{Q}_{q}=\left(K_{1}\right)_{v^{(2)}}
$$

Moreover, it follows from (15) that

$$
\begin{equation*}
\left(K_{2 T^{\prime}}\right)_{\tilde{u}^{(j)}}=\left(K_{1 T}\right)_{\tilde{v}^{(j)}} \quad \text { for } \quad j=1,2 \tag{17}
\end{equation*}
$$

But, by our construction, $T$ is $\left(K_{1}\right)_{v^{(1)}}$-split and $\left(K_{1}\right)_{v^{(2)}}$-anisotropic. So,

$$
\left[\left(K_{1 T}\right)_{\tilde{v}^{(1)}}:\left(K_{1}\right)_{v^{(1)}}\right]=1 \quad \text { and } \quad\left[\left(K_{1 T}\right)_{\tilde{v}^{(2)}}:\left(K_{1}\right)_{v^{(2)}}\right] \neq 1
$$

This, in view of (17), contradicts (16). So, the elements $\gamma_{1}, \ldots, \gamma_{m}$ are not weakly contained in $\Gamma_{2}$, verifying condition $\left(C_{1}\right)$.

## 5. Arithmetic groups

In this section, we will treat the case where the Zariski-dense subgroups $\Gamma_{i} \subset G_{i}(F)$ are $S$-arithmetic. For our purposes, it is convenient to use the description of these subgroups introduced in [13], $\S 1$, and for the reader's convenience we briefly recall here the relevant definitions and results. So, let $G$ be a connected absolutely almost simple algebraic group defined over a field $F$ of characteristic zero, let $\bar{G}$ be the corresponding adjoint group, and let $\pi: G \rightarrow \bar{G}$ be the natural isogeny. Suppose we are given:

- a number field $K$ together with a fixed embedding $K \hookrightarrow F$;
- an $F / K$-form $\mathscr{G}$ of $\bar{G}$ (which means that the group ${ }_{F} \mathscr{G}$ obtained by the base change $K \hookrightarrow F$ is $F$-isomorphic to $\bar{G}$ );
- a finite set $S$ of places of $K$ that contains $V_{K}^{\infty}$ but does not contain any nonarchimedean places where $\mathscr{G}$ is anisotropic.
We then have an embedding $\iota: \mathscr{G}(K) \hookrightarrow \bar{G}(F)$, which is well-defined up to an $F$ automorphism of $\bar{G}$. Now, let $\mathscr{O}_{K}(S)$ be the ring of $S$-integers in $K$ (with $\mathscr{O}_{K}=$ $\mathscr{O}_{K}\left(V_{K}^{\infty}\right)$ denoting the ring of algebraic integers in $K$ ). Fix a $K$-embedding $\mathscr{G} \hookrightarrow \mathrm{GL}_{n}$, and set $\mathscr{G}\left(\mathscr{O}_{K}(S)\right)=\mathscr{G}(K) \cap \mathrm{GL}_{n}\left(\mathscr{O}_{K}(S)\right)$. A subgroup $\Gamma \subset G(F)$ is called $(\mathscr{G}, K, S)$ arithmetic if $\pi(\Gamma)$ is commensurable with $\sigma\left(\iota\left(\mathscr{G}\left(\mathscr{O}_{K}(S)\right)\right)\right)$ for some $F$-automorphism $\sigma$ of $\bar{G}$. As usual, $\left(\mathscr{G}, K, V_{K}^{\infty}\right)$-arithmetic subgroups will simply be called $(\mathscr{G}, K)$-arithmetic. We recall (Lemma 2.6 of [13]) that if $\Gamma \subset G(F)$ is a Zariski-dense ( $\mathscr{G}, K, S)$-arithmetic subgroup then the trace field $K_{\Gamma}$ coincides with $K$.

Now, for $i=1,2$, let $G_{i}$ be a connected absolutely simple $F$-group of adjoint type. We will say that the subgroups $\Gamma_{i} \subset G_{i}(F)$ are commensurable up to an $F$-isomorphism between $G_{1}$ and $G_{2}$ if there exists an $F$-isomorphism $\sigma: G_{1} \rightarrow G_{2}$ such that $\sigma\left(\Gamma_{1}\right)$ is commensurable with $\Gamma_{2}$ in the usual sense, i.e. their intersection is of finite index in both of them. According to Proposition 2.5 of [13], if $\Gamma_{i}$ is a Zariski-dense $\left(\mathscr{G}_{i}, K_{i}, S_{i}\right)$ arithmetic subgroup of $G_{i}(F)$ for $i=1,2$, then $\Gamma_{1}$ and $\Gamma_{2}$ are commensurable up to an $F$-isomorphism between $G_{1}$ and $G_{2}$ if and only if $K_{1}=K_{2}=: K, S_{1}=S_{2}$ and $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are $K$-isomorphic.

In this section, unless stated otherwise, we will assume that the absolute Weyl groups of $G_{1}$ and $G_{2}$ are of equal order.

Theorem 5.1. Let $G_{1}$ and $G_{2}$ be connected absolutely simple algebraic groups of adjoint type defined over a field $F$ of characteristic zero such that $w_{1}=w_{2}$, and let $\Gamma_{i} \subset G_{i}(F)$ be a Zariski-dense $\left(\mathscr{G}_{i}, K_{i}, S_{i}\right)$-arithmetic subgroup for $i=1,2$. Furthermore, let $L_{i}$ be the minimal Galois extension of $K_{i}$ over which $\mathscr{G}_{i}$ becomes an inner form. Then, unless all of the following conditions are satisfied:
(a) $K_{1}=K_{2}=: K$,
(b) $\mathrm{rk}_{K_{v}} \mathscr{G}_{1}=\mathrm{rk}_{K_{v}} \mathscr{G}_{2}$ for all $v \in V^{K}$,
(c) $L_{1}=L_{2}$,
(d) $S_{1}=S_{2}$,
condition $\left(C_{i}\right)$ holds for at least one $i \in\{1,2\}$.
Proof. (a): Since the trace field $K_{\Gamma_{i}}$ coincides with $K_{i}$, our assertion in case (a) fails to hold follows from Theorem 4.2, So, in the rest of the proof we may (and we will) assume that $K_{1}=K_{2}=: K$. Then $\Gamma_{i} \subset \mathscr{G}_{i}(K)$ for $i=1,2$.
(b): Suppose that for some $v_{0} \in V^{K}$ we have

$$
\begin{equation*}
\mathrm{rk}_{K_{v_{0}}} \mathscr{G}_{1}>\mathrm{rk}_{K_{v_{0}}} \mathscr{G}_{2} . \tag{18}
\end{equation*}
$$

We will now show that condition $\left(C_{1}\right)$ holds. Set $V=S_{1} \cup\left\{v_{0}\right\}$, and for each $v \in V$ pick a maximal $K_{v}$-torus $T^{(v)}$ of $\mathscr{G}_{1}$ satisfying $\operatorname{rk}_{K_{v}} T^{(v)}=\operatorname{rk}_{K_{v}} \mathscr{G}_{1}$. Given $m \geqslant 1$, we can use Theorem 3.3 to find maximal $K$-tori $T_{1}, \ldots, T_{m}$ of $\mathscr{G}_{1}$ that are independent over $L_{1}$ and satisfy the following properties for each $i \leqslant m$ :

- $\theta_{T_{i}}\left(\operatorname{Gal}\left(L_{1 T_{i}} / L_{1}\right)\right)=W\left(\mathscr{G}_{1}, T_{i}\right) ;$
- $T_{i}$ is conjugate to $T^{(v)}$ by an element of $\mathscr{G}_{1}\left(K_{v}\right)$ for all $v \in V$.

We recall that by Dirichlet's Theorem (cf. [7], Theorem 5.12), for a $K$-torus $T$ and a finite subset $S$ of $V^{K}$ containing $V_{\infty}^{K}$ we have

$$
T\left(\mathscr{O}_{K}(S)\right) \simeq H \times \mathbb{Z}^{d_{T}(S)-\mathrm{rk}_{K} T},
$$

where $H$ is a finite group and $d_{T}(S)=\sum_{v \in S} \mathrm{rk}_{K_{v}} T$. Since $\Gamma_{1}$ has been assumed to be Zariski-dense in $\mathscr{G}_{1}$, it is infinite, and hence, $\sum_{v \in S_{1}} \mathrm{rk}_{K_{v}} \mathscr{G}_{1}>0$. Now we have

$$
d_{T_{i}}\left(S_{1}\right):=\sum_{v \in S_{1}} \mathrm{rk}_{K_{v}} T_{i}=\sum_{v \in S_{1}} \mathrm{rk}_{K_{v}} \mathscr{G}_{1}>0 .
$$

As $T_{i}$ is clearly $K$-anisotropic, we conclude from the above that the group $T_{i}\left(\mathscr{O}_{K}\left(S_{1}\right)\right)$ contains a subgroup isomorphic to $\mathbb{Z}^{d_{T_{i}}\left(S_{1}\right)}$, and so, in particular, one can find an element $\gamma_{i} \in \Gamma_{1} \cap T_{i}(K)$ of infinite order. We will use the elements $\gamma_{1}, \ldots, \gamma_{m}$ to verify property $\left(C_{1}\right)$. Indeed, these elements are multiplicatively independent by Lemma 2.1. and it remains to show that they are not weakly contained in $\Gamma_{2}$. Otherwise, there would exist a relation of the form

$$
\begin{equation*}
\chi_{1}\left(\gamma_{1}\right) \cdots \chi_{m}\left(\gamma_{m}\right)=\chi_{1}^{(2)}\left(\gamma_{1}^{(2)}\right) \cdots \chi_{m_{2}}^{(2)}\left(\gamma_{m_{2}}^{(2)}\right) \neq 1 \tag{19}
\end{equation*}
$$

for some semi-simple elements $\gamma_{1}^{(2)}, \ldots, \gamma_{m_{2}}^{(2)} \in \Gamma_{2} \subset \mathscr{G}_{2}(K)$, some characters $\chi_{i} \in X\left(T_{i}\right)$, some tori $T_{j}^{(2)} \subset \mathscr{G}_{2}$ such that $\gamma_{j}^{(2)} \in T_{j}^{(2)}(K)$ and some characters $\chi_{j}^{(2)} \in X\left(T_{j}^{(2)}\right)$. Since $w_{1}=w_{2}$ and therefore $G_{1}$ and $G_{2}$ have the same absolute rank, it would follow from Theorem [2.3] that for some $i \leqslant m$ and $j \leqslant m_{2}$ there is a $K$-isogeny $T_{j}^{(2)} \rightarrow T_{i}$, and therefore

$$
\mathrm{rk}_{K_{v_{0}}} T_{i}=\mathrm{rk}_{K_{v_{0}}} T_{j}^{(2)}
$$

Since by our choice

$$
\mathrm{rk}_{K_{v_{0}}} T_{i}=\operatorname{rk}_{K_{v_{0}}} \mathscr{G}_{1} \quad \text { and } \quad \mathrm{rk}_{K_{v_{0}}} T_{j}^{(2)} \leqslant \mathrm{rk}_{K_{v_{0}}} \mathscr{G}_{2},
$$

this would contradict (18).
(c): Let us show that $L_{1}=L_{2}$ automatically follows from the fact that

$$
\begin{equation*}
\mathrm{rk}_{K_{v}} \mathscr{G}_{1}=\mathrm{rk}_{K_{v}} \mathscr{G}_{2} \text { for all } v \in V^{K} \tag{20}
\end{equation*}
$$

(which we may assume in view of (b)). By symmetry, it is enough to establish the inclusion $L_{1} \subset L_{2}$. Assume the contrary. Then for the finite Galois extension $L:=L_{1} L_{2}$ of $K$ we can find a nontrivial element $\sigma \in \operatorname{Gal}\left(L / L_{2}\right) \subset \operatorname{Gal}(L / K)$. According to Theorem 6.7 of [7], there exists a finite subset $S$ of $V^{K}$ such that for any $v \in V^{K} \backslash S$, the group $\mathscr{G}_{2}$ is quasi-split over $K_{v}$. Furthermore, by Chebotarev's Density Theorem, there exists a nonarchimedean place $v \in V^{K} \backslash S$ with the property that for its extension $\bar{v}$ to $L$, the field extension $L_{\bar{v}} / K_{v}$ is unramified and its Frobenius automorphism $\operatorname{Fr}\left(L_{\bar{v}} \mid K_{v}\right)$ is $\sigma$. Then $L_{2} \subset K_{v}$, and therefore $\mathscr{G}_{2}$ is $K_{v}$-split. On the other hand, $L_{1} \not \subset K_{v}$, implying that $\mathscr{G}_{1}$ is not $K_{v}$-split. Since $G_{1}$ and $G_{2}$ have the same absolute rank (as $w_{1}=w_{2}$ ), this contradicts (20).
(d): If $S_{1} \neq S_{2}$ then, by symmetry, we can assume that there exists $v_{0} \in S_{1} \backslash S_{2}$ (any such $v_{0}$ is automatically nonarchimedean). We will show that then condition $\left(C_{1}\right)$ holds. As in part (b), for a given $m \geqslant 1$, we can pick maximal $K$-tori $T_{1}, \ldots, T_{m}$ of $\mathscr{G}_{1}$ so that they are independent over $L_{1}$ and satisfy the following conditions for each $i \leqslant m$ :

- $\theta_{T_{i}}\left(\operatorname{Gal}\left(L_{1 T_{i}} / L_{1}\right)\right)=W\left(\mathscr{G}_{1}, T_{i}\right) ;$
- $\mathrm{rk}_{K_{v_{0}}} T_{i}=\mathrm{rk}_{K_{v_{0}}} \mathscr{G}_{1}$.

Due to our convention that $S_{1}$ does not contain any nonarchimedean anisotropic places for $\mathscr{G}_{1}$, we have $\operatorname{rk}_{K_{v_{0}}} T_{i}=\operatorname{rk}_{K_{v_{0}}} \mathscr{G}_{1}>0$, hence

$$
d_{T_{i}}\left(S_{1} \backslash\left\{v_{0}\right\}\right)<d_{T_{i}}\left(S_{1}\right)
$$

Consequently, it follows from Dirichlet's Theorem (cf. (b)) that one can pick $\gamma_{i} \in \Gamma_{1} \cap$ $T_{i}\left(\mathscr{O}_{K}\left(S_{1}\right)\right)$ so that its image in $T_{i}\left(\mathscr{O}_{K}\left(S_{1}\right)\right) / T_{i}\left(\mathscr{O}_{K}\left(S_{1} \backslash\left\{v_{0}\right\}\right)\right)$ has infinite order for $i=1, \ldots, m$. We claim that the elements $\gamma_{1}, \ldots, \gamma_{m}$ verify property $\left(C_{1}\right)$.

As in (b), these elements are multiplicatively independent by Lemma 2.1, and we only need to show that they are not weakly contained in $\Gamma_{2}$. Assume the contrary. Then there exists a relation of the form (19) as in (b). Invoking Lemma 2.2, we see that there exist $i \leqslant m$ and $d_{i}>0$ such that for any $\lambda_{i} \in d_{i} X\left(T_{i}\right)$ there is a relation of the form

$$
\begin{equation*}
\lambda_{i}\left(\gamma_{i}\right)=\prod_{j=1}^{m_{2}} \lambda_{j}^{(2)}\left(\gamma_{j}^{(2)}\right) \tag{21}
\end{equation*}
$$

with $\lambda_{j}^{(2)} \in X\left(T_{j}^{(2)}\right)$. On the other hand, by our construction the image of $\gamma_{i}$ in $T_{i}\left(\mathscr{O}_{K}\left(S_{1}\right)\right) / T_{i}\left(\mathscr{O}_{K}\left(S_{1} \backslash\left\{v_{0}\right\}\right)\right)$ has infinite order, and therefore the subgroup $\left\langle\gamma_{i}\right\rangle$ is unbounded in $T_{i}\left(K_{v_{0}}\right)$. It follows that there exists $\lambda_{i} \in d_{i} X\left(T_{i}\right)$ for which $\lambda_{i}\left(\gamma_{i}\right) \in \overline{K_{v_{0}}}$ is not a unit (with respect to the extension of $v_{0}$ ). Pick for this $\lambda_{i}$ the corresponding expression (21). Since $v_{0} \notin S_{2}$, for each $j \leqslant m_{2}$, the subgroup $\left\langle\gamma_{j}^{(2)}\right\rangle$ is bounded in $T_{j}^{(2)}\left(K_{v_{0}}\right)$. Hence, the value $\lambda_{j}^{(2)}\left(\gamma_{j}^{(2)}\right) \in \overline{K_{v_{0}}}$ is a unit. Then (21) leads to a contradiction.

Remark 5.2. The argument used in parts (b) and (d) actually proves the following: Let $G_{1}$ and $G_{2}$ be absolutely simple algebraic groups defined over a field $F$ of characteristic zero such that $w_{1}=w_{2}$, and let $\Gamma_{i} \subset G_{i}(F)$ be a Zariski-dense ( $\mathscr{G}_{i}, K, S_{i}$ )-arithmetic subgroup for $i=1,2$. Furthermore, let $V$ be a finite subset of $V^{K}$ containing $S_{1}$ and let $L$ be a finite extension of $K$. If condition $\left(C_{1}\right)$ does not hold then there exists a maximal $K$-torus $T_{1}$ of $\mathscr{G}_{1}$ satisfying $\theta_{T_{1}}\left(\operatorname{Gal}\left(L_{T_{1}} / L\right)\right) \supset W\left(\mathscr{G}_{1}, T_{1}\right)$ and $\mathrm{rk}_{K_{v}} T_{1}=\mathrm{rk}_{K_{v}} \mathscr{G}_{1}$ for all $v \in V$ such that for some maximal $K$-torus $T_{2}$ of $\mathscr{G}_{2}$ there is a $K$-isogeny $T_{2} \rightarrow T_{1}$. We will use this statement below.

Here is an algebraic counterpart of Theorem 2 of the introduction.
Theorem 5.3. Let $G_{1}$ and $G_{2}$ be two connected absolutely simple algebraic groups of the same Killing-Cartan type different from $A_{n}, D_{2 n+1}(n>1)$ and $E_{6}$, defined over a field $F$ of characteristic zero, and let $\Gamma_{i} \subset G_{i}(F)$ be a Zariski-dense ( $\left.\mathscr{G}_{i}, K_{i}, S_{i}\right)$-arithmetic subgroup for $i=1,2$. If $\Gamma_{1}$ and $\Gamma_{2}$ are not commensurable (up to an $F$-isomorphism between $G_{1}$ and $G_{2}$ ) then condition $\left(C_{i}\right)$ holds for at least one $i \in\{1,2\}$.
Proof. If either $K_{1} \neq K_{2}$ or $S_{1} \neq S_{2}$, condition $\left(C_{i}\right)$ for some $i \in\{1,2\}$ holds by Theorem 5.1. So, we may assume that

$$
\begin{equation*}
K_{1}=K_{2}=: K \quad \text { and } \quad S_{1}=S_{2}=S . \tag{22}
\end{equation*}
$$

We first treat the case where the common type of $G_{1}$ and $G_{2}$ is not $D_{2 n}(n \geqslant 2)$, i.e. it is one of the following: $A_{1}, B_{n}, C_{n}(n \geqslant 2), E_{7}, E_{8}, F_{4}, G_{2}$. According to Theorem 5.1(b), if $\mathrm{rk}_{K_{v}} \mathscr{G}_{1} \neq \mathrm{rk}_{K_{v}} \mathscr{G}_{2}$ for at least one $v \in V^{K}$, then condition $\left(C_{i}\right)$ again holds for at least one $i \in\{1,2\}$. Thus, we may assume that

$$
\begin{equation*}
\mathrm{rk}_{K_{v}} \mathscr{G}_{1}=\mathrm{rk}_{K_{v}} \mathscr{G}_{2} \quad \text { for all } \quad v \in V^{K} . \tag{23}
\end{equation*}
$$

As we discussed in (13), $\S 6$, proof of Theorem 4), for the types under consideration (23) implies that $\mathscr{G}_{1} \simeq \mathscr{G}_{2}$ over $K$, combining which with (22), we obtain that $\Gamma_{1}$ and $\Gamma_{2}$ are commensurable (cf. [13], Proposition 2.5).

Consideration of groups of type $D_{2 n}$ relies on some additional results. In an earlier version of this paper, these were derived from [14] for $n>2$ (and then Theorem 5.3 was also formulated for type $D_{2 n}$ with $n>2$ ). Recently, Skip Garibaldi [4] gave an alternate proof of the required fact which works for all $n \geqslant 2$ (including triality forms of type $D_{4}$ ). This led to the current (complete) form of Theorem 5.3 and also showed that groups of type $D_{4}$ do not need to be excluded in Theorem 4 of [13] and its (geometric) consequences (such as Theorem 8.16 of [13]). Here is the precise formulation of Garibaldi's result.

Theorem 5.4. (4, Theorem 14) Let $G_{1}$ and $G_{2}$ be connected absolutely simple adjoint groups of type $D_{2 n}$ for some $n \geqslant 2$ over a global field $K$ such that $G_{1}$ and $G_{2}$ have the same quasi-split inner form - i.e., the smallest Galois extension of $K$ over which $G_{1}$ is of inner type is the same as for $G_{2}$. If there exists a maximal torus $T_{i}$ in $G_{i}$ for $i=1$ and 2 such that
(1) there exists a $K_{\text {sep }}$-isomorphism $\phi: G_{1} \rightarrow G_{2}$ whose restriction to $T_{1}$ is a $K$-isomorphism $T_{1} \rightarrow T_{2}$; and
(2) there is a finite set $\mathcal{V}$ of places of $K$ such that:
(a) For all $v \notin \mathcal{V}, G_{1}$ and $G_{2}$ are quasi-split over $K_{v}$,
(b) For all $v \in \mathcal{V},\left(T_{i}\right)_{K_{v}}$ contains a maximal $K_{v}$-split subtorus in $\left(G_{i}\right)_{K_{v}}$;
then $G_{1}$ and $G_{2}$ are isomorphic over $K$.

We will actually use the following consequence of the preceding theorem.
Theorem 5.5. Let $G_{1}$ and $G_{2}$ be connected absolutely simple algebraic groups of type $D_{2 n}$ over a number field $K$ such that
(a) $\mathrm{rk}_{K_{v}} G_{1}=\mathrm{rk}_{K_{v}} G_{2}$ for all $v \in V^{K}$;
(b) $L_{1}=L_{2}$ where $L_{i}$ is the minimal Galois extension of $K$ over which $G_{i}$ becomes an inner form.
Let $\mathcal{V} \subset V^{K}$ be a finite set of places such that $G_{1}$ is quasi-split over $K_{v}$ for $v \in V^{K} \backslash \mathcal{V}$. Let $T_{1}$ be a maximal $K$-torus of $G_{1}$ satisfying
$(\alpha) \theta_{T_{1}}\left(\operatorname{Gal}\left(K_{T_{1}} / K\right)\right) \supset W\left(G_{1}, T_{1}\right)$,
$(\beta) \mathrm{rk}_{K_{v}} T_{1}=\mathrm{rk}_{K_{v}} G_{1}$ for all $v \in \mathcal{V}$.
If there exists a $K$-isogeny $\varphi: T_{2} \rightarrow T_{1}$ from a maximal $K$-torus $T_{2}$ of $G_{2}$, then $G_{1}$ and $G_{2}$ are isogenous over $K$.

To derive Theorem 5.5 from Theorem 5.4, we can assume that both $G_{1}$ and $G_{2}$ are adjoint. Now note that it follows from Lemma 4.3 in [13] that, due to condition $(\alpha)$, one can assume without any loss of generality that the comorphism $\varphi^{*}: X\left(T_{1}\right) \rightarrow X\left(T_{2}\right)$ satisfies $\varphi^{*}\left(\Phi\left(G_{1}, T_{1}\right)\right)=\Phi\left(G_{2}, T_{2}\right)$. Then $\varphi$ is actually a $K$-isomorphism of tori that extends to a $\bar{K}$-isomorphism $\phi: G_{2} \rightarrow G_{1}$. So, we can use Theorem 5.4 to obtain Theorem 5.5.

To complete the proof of Theorem5.3, we observe that if neither $\left(C_{1}\right)$ nor $\left(C_{2}\right)$ holds, then according to Theorem 5.1, conditions (a) and (b) of Theorem 5.5 are satisfied for $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$. Fix a finite set of places $V \subset V^{K}$ that contains $S_{1}$ and is big enough so that $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are quasi-split over $K_{v}$ for all $v \in V^{K} \backslash V$. Using Remark 5.2, we can find a maximal $K$-torus $T_{1}$ of $\mathscr{G}_{1}$ that satisfies conditions $(\alpha)$ and $(\beta)$ of Theorem 5.5 and a maximal $K$-torus $T_{2}$ of $G_{2}$ which is isogeneous to $T_{1}$ over $K$. Then $\mathscr{G}_{1} \simeq \mathscr{G}_{2}$ over $K$ by Theorem 5.5, making $\Gamma_{1}$ and $\Gamma_{2}$ commensurable as above.

Our next result contains more restrictions on the arithmetic groups $\Gamma_{1}$ and $\Gamma_{2}$ given the fact that both the conditions $\left(C_{1}\right)$ and $\left(C_{2}\right)$ fail to hold.

Theorem 5.6. Let $G_{1}$ and $G_{2}$ be two connected absolutely simple algebraic groups over a field $F$ of characteristic zero such that $w_{1}=w_{2}$, and let $\Gamma_{i} \subset G_{i}(F)$ be a Zariskidense $\left(\mathscr{G}_{i}, K, S\right)$-arithmetic subgroup for $i=1,2$. If both $\left(C_{1}\right)$ and $\left(C_{2}\right)$ fail to hold, then $\operatorname{rk}_{K} \mathscr{G}_{1}=\mathrm{rk}_{K} \mathscr{G}_{2}$. Moreover, if $G_{1}$ and $G_{2}$ are of the same Killing-Cartan type, then the Tits indices $\mathscr{G}_{1} / K_{v}$ and $\mathscr{G}_{2} / K_{v}$ are isomorphic for all $v \in V^{K}$, and the Tits indices $\mathscr{G}_{1} / K$ and $\mathscr{G}_{2} / K$ are isomorphic.

Proof. The proof relies on the following statement which was actually established in [13], $\S 7$ (although it was not stated there explicitly).

Theorem 5.7. Let $G_{1}$ and $G_{2}$ be two connected absolutely simple algebraic $K$-groups, let $L_{i}$ be the minimal Galois extension of $K$ over which $G_{i}$ are of inner type, and let $\mathcal{V}$ be a finite subset of $V^{K}$ such that both $G_{1}$ and $G_{2}$ are $K_{v}$-quasi-split for all $v \notin \mathcal{V}$. Furthermore, let $T_{i}$ be a maximal $K$-torus of $G_{i}$, where $i=1,2$, such that
(1) $\theta_{T_{i}}\left(\operatorname{Gal}\left(K_{T_{i}} / K\right)\right) \supset W\left(G_{i}, T_{i}\right)$;
(2) $\mathrm{rk}_{K_{v}} T_{i}=\mathrm{rk}_{K_{v}} G_{i}$ for all $v \in \mathcal{V}$.

If $L_{1}=L_{2}$ and there exists a $K$-isogeny $T_{1} \rightarrow T_{2}$, then $\mathrm{rk}_{K} G_{1}=\mathrm{rk}_{K} G_{2}$. Moreover, if $G_{1}$ and $G_{2}$ are of the same Killing-Cartan type then the Tits indices $G_{1} / K_{v}$ and $G_{2} / K_{v}$ are isomorphic for all $v \in V^{K}$, and the Tits indices of $G_{1} / K$ and $G_{2} / K$ are isomorphic.

For the reader's convenience, we will give a proof of this theorem in the Appendix.
To derive Theorem 5.6 from Theorem 5.7, we basically mimic the argument used to consider type $D_{2 n}$ in Theorem5.3. More precisely, we pick a finite set $V$ of places of $K$ containing $S_{1}$ so that the groups $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are quasi-split over $K_{v}$ for all $v \in V^{K} \backslash V$. Since by our assumption both $\left(C_{1}\right)$ and $\left(C_{2}\right)$ fail to hold, we can use Remark 5.2 to find of maximal $K$-torus $T_{1}$ of $\mathscr{G}_{1}$ that satisfies conditions (1) and (2) of Theorem 5.7 for $i=1$, and a maximal $K$-torus $T_{2}$ of $\mathscr{G}_{2}$ which is isogeneous to $T_{1}$ over $K$. Since $\mathrm{rk}_{K_{v}} \mathscr{G}_{1}=\mathrm{rk}_{K_{v}} \mathscr{G}_{2}$, we obtain that condition (2) holds also for $i=2$. Furthermore, condition (1) for $i=1$ combined with the fact that $L_{1}=L_{2}$, by order consideration, yields that the inclusion $\theta_{T_{2}}\left(\operatorname{Gal}\left(L_{2 T_{2}} / L_{2}\right)\right) \subset W\left(\mathscr{G}_{2}, T_{2}\right)$ is in fact an equality, so (2) holds for $i=2$ as well. Now, applying Theorem 5.7 we obtain Theorem 5.6.

We conclude this section with a variant of Theorem 5.6 which has an interesting geometric application (see Theorem 5 in the Introduction; this theorem will be proved in 97$)$. Let $\Gamma_{i}$ is a Zariski-dense $\left(\mathscr{G}_{i}, K_{i}, S_{i}\right)$-arithmetic subgroup of $G_{i}$, and assume that $\mathscr{G}_{1}$ is $K_{1}$-isotropic and $\mathscr{G}_{2}$ is $K_{2}$-anisotropic. It follows from Theorem 5.1 (for $K_{1} \neq K_{2}$ ) and Theorem 5.6 (for $K_{1}=K_{2}$ ) that then condition $\left(C_{i}\right)$ holds for at least one $i \in\{1,2\}$. In fact, assuming that $w_{1}=w_{2}$, one can always guarantee that condition $\left(C_{1}\right)$ holds:

Theorem 5.8. Let $G_{1}$ and $G_{2}$ be two connected absolutely simple algebraic groups with $w_{1}=w_{2}$. Let $\Gamma_{i}$ be a Zariski-dense $\left(\mathscr{G}_{i}, K_{i}, S_{i}\right)$-arithmetic subgroup of $G_{i}$ for $i=1,2$, and assume that $\mathscr{G}_{1}$ is $K_{1}$-isotropic and $\mathscr{G}_{2}$ is $K_{2}$-anisotropic. Then property $\left(C_{1}\right)$ holds.

The proof relies on the following version of Theorem 5.7 which treats the case where the fields of definitions of $\Gamma_{1}$ and $\Gamma_{2}$ are not necessarily the same.

Theorem 5.7. For $i=1,2$, let $G_{i}$ be a connected absolutely simple algebraic group over a number field $K_{i}$, and let $L_{i}$ be the minimal Galois extension of $K_{i}$ over which $G_{i}$ is of inner type. Assume that $K_{1} \subset K_{2}, L_{2} \subset K_{2} L_{1}, w_{1}=w_{2}$ and $\mathrm{rk}_{K_{1}} G_{1}>0$. Furthermore, let $\mathcal{V}_{1} \subset V^{K_{1}}$ be a finite subset such that $G_{2}$ is quasi-split over $K_{2 v}$ for
all $v \notin \mathcal{V}_{2}$, where $\mathcal{V}_{2}$ consists of all extensions of places contained in $\mathcal{V}_{1}$ to $K_{2}$, and let $T_{1}$ be a maximal $K_{1}$-torus of $G_{1}$ such that
(1) $\theta_{T_{1}}\left(\operatorname{Gal}\left(K_{1 T_{1}} / K_{1}\right)\right) \supset W\left(G_{1}, T_{1}\right)$;
(2) $\mathrm{rk}_{K_{1 v}} T_{1}=\mathrm{rk}_{K_{1 v}} G_{1}$ for all $v \in \mathcal{V}_{1}$.

If there exists a maximal torus $T_{2}$ of $G_{2}$ and a $K_{2}$-isogeny $T_{2} \rightarrow T_{1}$, then $\mathrm{rk}_{K_{2}} G_{2}>0$.
This result is also proved in the Appendix along with Theorem 5.7.
Proof of Theorem 5.8. If $K_{1} \not \subset K_{2}$ then the fact that $\left(C_{1}\right)$ holds follows from Theorem 4.2 (cf. the proof of Theorem [5.1(a)). So, in the rest of the argument we may assume that $K_{1} \subset K_{2}$.

Next, suppose that $L_{2} \not \subset K_{2} L_{1}$. In this case, the argument imitates the proof of Theorem 5.1(c). More precisely, we have $K_{2} L_{1} \varsubsetneqq L_{1} L_{2}$. So, if $\mathfrak{L}$ is the normal closure of $L_{1} L_{2}$ over $K_{1}$, then there exists $\sigma \in \operatorname{Gal}\left(\mathfrak{L} / K_{1}\right)$ that restricts trivially to $K_{2} L_{1}$ and nontrivially to $L_{1} L_{2}$. By Chebotarev's Density Theorem, we can find $v_{0} \in V^{K_{1}} \backslash S_{1}$ which is unramified in $\mathfrak{L} / K_{1}$ and for which the Frobenius automorphism $\operatorname{Fr}\left(\tilde{v}_{0} \mid v_{0}\right)$ equals $\sigma$ for an appropriate extension $\tilde{v}_{0} \mid v_{0}$, and in addition the group $\mathscr{G}_{1}$ is quasi-split over $K_{1 v_{0}}$. Let $u_{0}$ be the restriction of $\tilde{v}_{0}$ to $K_{2}$. By construction, we have $L_{1} \subset K_{1 v_{0}}$, which means that $\mathscr{G}_{1}$ is actually split over $K_{1 v_{0}}$; at the same time, $L_{2} \not \subset K_{2 u_{0}}$, and therefore $\mathscr{G}_{2}$ is not split over $K_{2 u_{0}}$. Set $L=L_{1} L_{2}$ and $\mathcal{V}_{1}=S_{1} \cup\left\{v_{0}\right\}$. Fix $m \geqslant 1$, and using Theorem 3.3 pick maximal $K_{1}$-tori $T_{1}, \ldots, T_{m}$ of $\mathscr{G}_{1}$ that are independent over $L$ and satisfy the following two conditions for each $j \leqslant m$ :

- $\theta_{T_{j}}\left(\operatorname{Gal}\left(L_{T_{j}} / L\right)\right)=W\left(G_{1}, T_{j}\right) ;$
- $\mathrm{rk}_{K_{1 v}} T_{j}=\mathrm{rk}_{K_{1 v}} \mathscr{G}_{1}$ for all $v \in \mathcal{V}_{1}$.

As in the proof of Theorem 5.1(b), it follows from Dirichlet's Theorem that one can pick elements $\gamma_{j} \in \Gamma_{1} \cap T_{j}\left(K_{1}\right)$ for $j \leqslant m$ of infinite order. By Lemma 2.1, the elements $\gamma_{1}, \ldots, \gamma_{m}$ are multiplicatively independent, so to establish property $\left(C_{1}\right)$ in the case at hand, it remains to show that these elements are not weakly contained in $\Gamma_{2}$. Assume the contrary. Then according to Theorem 2.3 (with $K=K_{2}$ ), there exists a maximal $K_{2}$-torus $T^{(2)}$ of $\mathscr{G}_{2}$ and a $K_{2}$-isogeny $T^{(2)} \rightarrow T_{j}$ for some $j \leqslant m$. Clearly, $T_{j}$ is split over $K_{1 v_{0}}$, hence also over $K_{2 u_{0}}$. We conclude that $T^{(2)}$ is also split over $K_{2 u_{0}}$, which is impossible as $\mathscr{G}_{2}$ is not $K_{2 u_{0}}$-split. This verifies property $\left(C_{1}\right)$ in this case. (We note that so far we have not used the assumption that $\mathscr{G}_{1}$ is $K_{1}$-isotropic and $\mathscr{G}_{2}$ is $K_{2}$-anisotropic.)

It remains to consider the case where $K_{1} \subset K_{2}$ and $L_{2} \subset K_{2} L_{1}$. Here the argument is very similar to the one given above but uses a different choice of the set $\mathcal{V}_{1}$ and relies on Theorem 5.7. More precisely, pick a finite subset $\mathcal{V}_{1} \subset V^{K_{1}}$ containing $S_{1}$ so that $\mathscr{G}_{2}$ is quasi-split over $K_{2 v}$ for all $v \in \mathcal{V}_{2}$, where $\mathcal{V}_{2}$ consists of all extensions of places in $\mathcal{V}_{1}$ to $K_{2}$. Assume that $\left(C_{1}\right)$ does not hold, i.e., there exists $m \geqslant 1$ such that any $m$ multiplicatively independent semi-simple elements of $\Gamma_{1}$ of infinite order are necessarily weakly contained in $\Gamma_{2}$. Fix such an $m$, and using the same $L$ as above, pick maximal $K_{1}$-tori $T_{1}, \ldots, T_{m}$ of $\mathscr{G}_{1}$ that are independent over $L$ and satisfy the above bulleted conditions for this new choice of $\mathcal{V}_{1}$. Arguing as in the previous paragraph, we see that
again, there exists a maximal $K_{2}$-torus $T^{(2)}$ of $\mathscr{G}_{2}$ and a $K_{2}$-isogeny $T^{(2)} \rightarrow T_{j}$ for some $j \leqslant m$. Then it follows from Theorem 5.7 that $\mathscr{G}_{2}$ is $K_{2}$-isotropic, a contradiction.

It would be interesting to determine if the assumption that $w_{1}=w_{2}$ in Theorem 5.8 can be omitted.

Question. Is it possible to construct $K_{1}$-isotropic $\mathscr{G}_{1}$ and $K_{2}$-anisotropic $\mathscr{G}_{2}$, with $K_{1} \subset K_{2}$ so that every $K_{1}$-anisotropic torus of $\mathscr{G}_{1}$ is $K_{2}$-isomorphic to a $K_{2}$-torus of $\mathscr{G}_{2}$ ?
(Obviously, the affirmative answer to this question with $K_{1}=\mathbb{Q}$ would lead to an example where every semi-simple element of infinite order in $\Gamma_{1}$ would be weakly contained in $\Gamma_{2}$ and therefore ( $C_{1}$ ) would not hold.)

## 6. Groups of types $A_{n}, D_{n}$ and $E_{6}$

It is known that the assertion of Theorem 5.3 may fail if the common Killing-Cartan type of the groups $G_{1}$ and $G_{2}$ is one of the following: $A_{n}, D_{2 n+1}(n>1)$ or $E_{6}$ (cf. Examples 6.5, 6.6, 6.7 and $\S 9$ in [13]). Nevertheless, a suitable analog of Theorem 5.3 with interesting geometric consequences can still be given (cf. Theorem 6.6 below). It is based on the following notion.
Definition. Let $G_{1}$ and $G_{2}$ be connected absolutely almost simple algebraic groups defined over a field $K$. We say that $G_{1}$ and $G_{2}$ have equivalent systems of maximal $K$ tori if for every maximal $K$-torus $T_{1}$ of $G_{1}$ there exists a $\bar{K}$-isomorphism $\varphi: G_{1} \rightarrow G_{2}$ such that the restriction $\left.\varphi\right|_{T_{1}}$ is defined over $K$, and conversely, for every maximal $K$-torus $T_{2}$ of $G_{2}$ there exists a $\bar{K}$-isomorphism $\psi: G_{2} \rightarrow G_{1}$ such that the restriction $\left.\psi\right|_{T_{2}}$ is defined over $K$.

We note that given a $\bar{K}$-isomorphism $\varphi: G_{1} \rightarrow G_{2}$ as in the definition, the torus $T_{2}=\varphi\left(T_{1}\right)$ is defined over $K$ and the corresponding map $X\left(T_{2}\right) \rightarrow X\left(T_{1}\right)$ induces a bijection $\Phi\left(G_{2}, T_{2}\right) \rightarrow \Phi\left(G_{1}, T_{1}\right)$. This observation implies that if $G_{i}$ is a connected absolutely almost simple real algebraic group, $\Gamma_{i} \subset G_{i}(\mathbb{R})$ is a torsion-free ( $\mathscr{G}_{i}, K$ )arithmetic subgroup and $\mathfrak{X}_{\Gamma_{i}}$ is the associated locally symmetric space, where $i=1,2$, then the fact that $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ have equivalent systems of maximal $K$-tori entails that $\mathfrak{X}_{\Gamma_{1}}$ and $\mathfrak{X}_{\Gamma_{2}}$ are length-commensurable (see Proposition 9.14 of [13]). For technical reasons, in this section it is more convenient for us to deal with simply connected groups rather than with adjoint ones which are more natural from the geometric standpoint. So, we observe in this regard that if simply connected $K$-groups $G_{1}$ and $G_{2}$ have equivalent systems of maximal $K$-tori then so do the corresponding adjoint groups $\bar{G}_{1}$ and $\bar{G}_{2}$ (and vice versa).

We will now describe fairly general conditions guaranteeing that two forms over a number field $K$, of an absolutely almost simple simply connected group of one of types $A_{n}, D_{2 n+1}(n>1)$, or $E_{6}$, have equivalent systems of maximal $K$-tori.

Theorem 6.1. Let $G_{1}$ and $G_{2}$ be two connected absolutely almost simple simply connected algebraic groups of one of the following types: $A_{n}, D_{2 n+1}(n>1)$ or $E_{6}$, defined
over a number field $K$, and let $L_{i}$ be the minimal Galois extension of $K$ over which $G_{i}$ is of inner type. Assume that

$$
\begin{equation*}
\mathrm{rk}_{K_{v}} G_{1}=\mathrm{rk}_{K_{v}} G_{2} \text { for all } v \in V^{K}, \tag{24}
\end{equation*}
$$

hence $2^{2} L_{1}=L_{2}=: L$. Moreover, if $G_{1}$ and $G_{2}$ are of type $D_{2 n+1}$ we assume that for each real place $v$ of $K$, we can find maximal $K_{v}$-tori $T_{i}^{v}$ of $G_{i}$ for $i=1,2$, such that $\mathrm{rk}_{K_{v}} T_{i}^{v}=\mathrm{rk}_{K_{v}} G_{i}$ and there exists a $K_{v}$-isomorphism $T_{1}^{v} \rightarrow T_{2}^{v}$ that extends to a $\overline{K_{v}}$-isomorphism $G_{1} \rightarrow G_{2}$. If
(1) one can pick maximal $K$-tori $T_{i}^{0}$ of $G_{i}$ for $i=1,2$ with a $K$-isomorphism $T_{1}^{0} \rightarrow T_{2}^{0}$ that extends to a $\bar{K}$-isomorphism $G_{1} \rightarrow G_{2}$, and
(2) there exists a place $v_{0}$ of $K$ such that one of the groups $G_{i}$ is $K_{v_{0}}$-anisotropic
(and then both are such due to (24)),
then $G_{1}$ and $G_{2}$ have equivalent systems of maximal $K$-tori.
Proof. We begin by establishing first the corresponding local assertion.
Lemma 6.2. Let $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ be two connected absolutely almost simple simply connected algebraic groups of one of the following types: $A_{\ell}(\ell \geqslant 1), D_{\ell}(\ell \geqslant 5)$ or $E_{6}$, over a nondiscrete locally compact field $\mathscr{K}$ of characteristic zero, and let $\mathscr{L}_{i}$ be the minimal Galois extension of $\mathscr{K}$ over which $\mathscr{G}_{i}$ is of inner type. Assume that

$$
\mathscr{L}_{1}=\mathscr{L}_{2}=: \mathscr{L} \quad \text { and } \operatorname{rk}_{\mathscr{K}} \mathscr{G}_{1}=\operatorname{rk}_{\mathscr{K}} \mathscr{G}_{2},
$$

and moreover, in case $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are of type $D_{\ell}$ and $\mathscr{K}=\mathbb{R}$, there exist maximal $\mathscr{K}$ tori $\mathscr{T}_{i}$ of $\mathscr{G}_{i}$ such that $\operatorname{rk}_{\mathscr{K}} \mathscr{T}_{i}=\operatorname{rk}_{\mathscr{K}} \mathscr{G}_{i}$ for $i=1,2$, with a $\mathscr{K}$-isomorphism $\mathscr{T}_{1} \rightarrow \mathscr{T}_{2}$ that extends to a $\overline{\mathscr{K}}$-isomorphism $\mathscr{G}_{1} \rightarrow \mathscr{G}_{2}$. Then
(i) except in the case where $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are inner $K$-forms of a split group of type $A_{\ell}$ with $\ell>1$, we have $\mathscr{G}_{1} \simeq \mathscr{G}_{2}$ over $\mathscr{K}$;
(ii) in all cases, $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ have equivalent systems of maximal $\mathscr{K}$-tori.

Proof. (i): First, let $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ be outer $\mathscr{K}$-forms of a split group of type $A_{\ell}$ associated with a quadratic extension $\mathscr{L}$ of $\mathscr{K}$. Then $\mathscr{G}_{i}=\operatorname{SU}\left(\mathscr{L}, h_{i}\right)$ where $h_{i}$ is a nondegenerate Hermitian form on $\mathscr{L}^{n}$, $n=\ell+1$, with respect to the nontrivial automorphism of $\mathscr{L} / \mathscr{K}$. Since $\mathrm{rk}_{\mathscr{K}} \mathscr{G}_{i}$ coincides with the Witt index of the Hermitian form $h_{i}$, the forms $h_{1}$ and $h_{2}$ have equal Witt index. On the other hand, it is well-known, and easy to see, that the similarity class of an anisotropic Hermitian form over $\mathscr{L}$ is determined by its dimension (which for nonarchimedean $v$ is necessarily $\leqslant 2$ ). So, the fact that $h_{1}$ and $h_{2}$ have equal Witt index implies that $h_{1}$ and $h_{2}$ are similar, hence $\mathscr{G}_{1} \simeq \mathscr{G}_{2}$, as required.

Now, suppose $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are of type $D_{\ell}$ with $\ell \geqslant 5$. If $\mathscr{K}=\mathbb{C}$ then there is nothing to prove; otherwise there is a unique quaternion central division algebra $\mathscr{D}$ over $\mathscr{K}$. For each $i \in\{1,2\}$, we have two possibilities: either $\mathscr{G}_{i}=\operatorname{Spin}_{n}\left(q_{i}\right)$ where $q_{i}$ is a nondegenerate quadratic form over $\mathscr{K}$ of dimension $n=2 \ell$ (orthogonal type), or $\mathscr{G}_{i}$ is the universal cover of $\operatorname{SU}\left(\mathscr{D}, h_{i}\right)$ where $h_{i}$ is a nondegenerate skew-Hermitian form on $\mathscr{D}^{\ell}$ with respect to the canonical involution on $\mathscr{D}$ (quaternionic type). We will now show

[^1]that in our situation, $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are both of the same, orthogonal or quaternionic, type. First, we treat the case where $\mathscr{K}$ is nonarchimedean. Assume that $\mathscr{G}_{1}$ is of orthogonal, and $\mathscr{G}_{2}$ is of quaternionic, type. Then $\operatorname{rk}_{\mathscr{K}} \mathscr{G}_{1} \geqslant(2 \ell-4) / 2=\ell-2$, while $\mathrm{rk}_{\mathscr{K}} \mathscr{G}_{2} \leqslant \ell / 2$. So, $\operatorname{rk}_{\mathscr{K}} \mathscr{G}_{1}=\operatorname{rk}_{\mathscr{K}} \mathscr{G}_{2}$ is impossible as $\ell \geqslant 5$, a contradiction. Over $\mathscr{K}=\mathbb{R}$, however, one can have $\mathscr{G}_{1}$ of orthogonal type and $\mathscr{G}_{2}$ of quaternionic type with the same $\mathscr{K}$ rank, so to prove our assertion in this case we need to use the hypothesis that there exist maximal $\mathscr{K}$-tori $\mathscr{T}_{i}$ of $\mathscr{G}_{i}$ such that $\mathrm{rk}_{\mathscr{K}} \mathscr{T}_{i}=\operatorname{rk}_{\mathscr{K}} \mathscr{G}_{i}$, with a $\mathscr{K}$-isomorphism $\mathscr{T}_{1} \rightarrow \mathscr{T}_{2}$ that extends to a $\overline{\mathscr{K}}$-isomorphism $\mathscr{G}_{1} \rightarrow \mathscr{G}_{2}$. Such an isomorphism induces an isomorphism between the Tits indices of $\mathscr{G}_{1} / \mathscr{K}$ and $\mathscr{G}_{2} / \mathscr{K}$ (cf. the discussion in $\S 7.1$ of [13]). However, if $\mathscr{G}_{1}$ is of orthogonal type, and $\mathscr{G}_{2}$ of quaternionic, the corresponding Tits indices are not isomorphic, and our assertion follows.

Now, let $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ be of quaternionic type. It is known that two nondegenerate skew-Hermitian forms over $\mathscr{D}$ are equivalent if they have the same dimension and in addition the same discriminant in the nonarchimedean case (cf. [16], Ch.10, Theorem 3.6 in the nonarchimedean case, and Theorem 3.7 in the archimedean case). If $h_{1}$ and $h_{2}$ are the skew-Hermitian forms defining $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ respectively, then the condition that $h_{1}$ and $h_{2}$ have the same discriminant is equivalent to the fact that $\mathscr{L}_{1}=\mathscr{L}_{2}$, and therefore holds in our situation. Thus, $h_{1}$ and $h_{2}$ are equivalent, hence $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are $\mathscr{K}$-isomorphic.

Next, let $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ be of orthogonal type, $\mathscr{G}_{i}=\operatorname{Spin}\left(q_{i}\right)$. To show that $\mathscr{G}_{1} \simeq \mathscr{G}_{2}$, it is enough to show that $q_{1}$ and $q_{2}$ are similar. The condition $\operatorname{rk}_{\mathscr{K}} \mathscr{G}_{1}=\operatorname{rk}_{\mathscr{K}} \mathscr{G}_{2}$ yields that $q_{1}$ and $q_{2}$ have the same Witt index, so we just need to show that the maximal anisotropic subforms $q_{1}^{a}$ and $q_{2}^{a}$ are similar. If $\mathscr{K}=\mathbb{R}$, then any two anisotropic forms of the same dimension are similar, and there is nothing to prove. Now, let $\mathscr{K}$ be nonarchimedean. Our claim is obvious if $q_{1}^{a}=q_{2}^{a}=0$; in the two remaining cases the common dimension of $q_{1}^{a}$ and $q_{2}^{a}$ can only be 2 or 4 . To treat binary forms, we observe that $q_{1}$ and $q_{2}$, hence also $q_{1}^{a}$ and $q_{2}^{a}$, have the same discriminant, and two binary forms of the same discriminant are similar. The claim for quaternary forms follows from the fact that there exists a single equivalence class of such anisotropic forms (this equivalence class is represented by the reduced-norm form of $\mathscr{D}$ ).

Finally, we consider groups of type $E_{6}$. If $\mathscr{K}=\mathbb{R}$ then by inspecting the tables in 18 we find that there are two possible indices for the inner forms with the corresponding groups having $\mathbb{R}$-ranks 2 and 6 , and there are three possible indices for outer forms for which the $\mathbb{R}$-ranks are 0,2 and 4 . Thus, since $G_{1}$ and $G_{2}$ are simultaneously either inner or outer forms and have the same $\mathbb{R}$-rank, they are $\mathbb{R}$-isomorphic. To establish the same conclusion in the nonarchimedean case, we recall that then an outer form of type $E_{6}$ is always quasi-split (cf. [7], Proposition 6.15), so for outer forms our assumption that $\mathscr{L}_{1}=\mathscr{L}_{2}$ implies that $G_{1} \simeq G_{2}$. Since there exists only one nonsplit inner form of type $E_{6}$ (this follows, for example, from the proof of Lemma 9.9(ii) in [13]), our assertion holds in this case as well.
(ii): It remains to be shown that if $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are inner forms of type $A_{\ell}$ over $\mathscr{K}$ such that $\operatorname{rk}_{\mathscr{K}} \mathscr{G}_{1}=\operatorname{rk}_{\mathscr{K}} \mathscr{G}_{2}$, then $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ have equivalent systems of maximal $\mathscr{K}$-tori. We have $\mathscr{G}_{i}=\mathrm{SL}_{d_{i}, \mathscr{D}_{i}}$ where $\mathscr{D}_{i}$ is a central division algebra over $\mathscr{K}$ of degree $n_{i}$ and

$$
\operatorname{rk}_{\mathscr{K}} \mathscr{G}_{i}=d_{i}-1 \quad \text { and } \quad d_{i} m_{i}=\ell+1=: n .
$$

Thus, in our situation $d_{1}=d_{2}$ and $n_{1}=n_{2}$. Furthermore, it is well-known (cf. [14], Proposition 2.6) that a commutative étale $n$-dimensional $\mathscr{K}$-algebra $\mathscr{E}=\prod_{j=1}^{s} \mathscr{E}^{(j)}$, where $\mathscr{E}^{(j)} / \mathscr{K}$ is a finite (separable) field extension, embeds in $\mathscr{A}_{i}:=M_{d_{i}}\left(\mathscr{D}_{i}\right)$ if and only if each degree $\left[\mathscr{E}^{(j)}: \mathscr{K}\right]$ is divisible by $n_{i}$. So, we conclude that $\mathscr{E}$ embeds in $\mathscr{A}_{1}$ if and only if it embeds in $\mathscr{A}_{2}$. On the other hand, any maximal $\mathscr{K}$-torus $\mathscr{T}_{1}$ of $\mathscr{G}_{1}$ coincides with the torus $\mathrm{R}_{\mathscr{E}_{1} / \mathscr{K}}^{(1)}\left(\mathrm{GL}_{1}\right)$ associated with the group of norm one elements in some $n$-dimensional commutative étale subalgebra $\mathscr{E}_{1}$ of $\mathscr{A}_{1}$. As we noted above, $\mathscr{E}_{1}$ embeds in $\mathscr{A}_{2}$, and then using the Skolem-Noether Theorem (see Footnote 1 on p. 592 in [14]) one can construct an isomorphism $\mathscr{A}_{1} \otimes \mathscr{K} \overline{\mathscr{K}} \simeq \mathscr{A}_{2} \otimes \mathscr{K} \overline{\mathscr{K}}$ that maps $\mathscr{E}_{1}$ to a subalgebra $\mathscr{E}_{2} \subset \mathscr{A}_{2}$. This isomorphism gives rise to a $\bar{K}$-isomorphism $\mathscr{G}_{1} \simeq \mathscr{G}_{2}$ that induces a $\mathscr{K}$-isomorphism between $\mathscr{T}_{1}$ and $\mathscr{T}_{2}:=\mathrm{R}_{\mathscr{E}_{2} / \mathscr{K}}\left(\mathrm{GL}_{1}\right)$. By symmetry, $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ have equivalent systems of maximal $\mathscr{K}$-tori.

To complete the proof of Theorem 6.1, we fix a $\bar{K}$-isomorphism $\varphi_{0}: G_{1} \rightarrow G_{2}$ such that the restriction $\left.\varphi_{0}\right|_{T_{1}^{0}}$ is a $K$-isomorphism between $T_{1}^{0}$ and $T_{2}^{0}$. Let $T_{1}$ be an arbitrary maximal $K$-torus of $G_{1}$. Then by Lemma 6.2, for any $v \in V^{K}$, there exists a $\overline{K_{v}}$ isomorphism $\varphi_{v}: G_{1} \rightarrow G_{2}$ whose restriction to $T_{1}$ is defined over $K_{v}$. Then $\varphi_{v}=\alpha \cdot \varphi_{0}$ for some $\alpha \in \operatorname{Aut} G_{2}$. There exists an automorphism of $G_{2}$ that acts as $t \mapsto t^{-1}$ on $T_{2}:=$ $\varphi_{v}\left(T_{1}\right)$. Moreover, for groups of the types listed in the theorem, this automorphism represents the only nontrivial element of Aut $G_{2} / \operatorname{Inn} G_{2}$. So, if necessary, we can replace $\varphi_{v}$ by the composite of $\varphi_{v}$ with this automorphism to ensure that $\alpha$ is inner (and the restriction of $\varphi_{v}$ to $T_{1}$ is still defined over $K$, cf. the proof of Lemma 9.7 in [13]). This shows that $T_{1}$ admits a coherent (relative to $\varphi_{0}$ ) $K_{v}$-embedding in $G_{2}$ (in the terminology introduced in [13], $\S 9)$, for every $v \in V^{K}$. Since $T_{1}$ is $K_{v_{0}}$-anisotropic, $\amalg^{2}\left(T_{1}\right)$ is trivial (cf. [7, Proposition 6.12). So, by Theorem 9.6 of [13], $T_{1}$ admits a coherent $K$-defined embedding in $G_{2}$ which in particular is a $K$-embedding $T_{1} \rightarrow G_{2}$ which extends to a $\bar{K}$-isomorphism $G_{1} \rightarrow G_{2}$. By symmetry, $G_{1}$ and $G_{2}$ have equivalent systems of maximal $K$-tori.

The following proposition complements Theorem 6.1 for groups of type $A_{n}$ in that it does not assume the existence of a place $v_{0} \in V^{K}$ where the groups are anisotropic.

Proposition 6.3. Let $G_{1}$ and $G_{2}$ be two connected absolutely almost simple simply connected algebraic groups of type $A_{n}$ over a number field $K$, and let $L_{i}$ be the minimal Galois extension of $K$ over which $G_{i}$ is of inner type. Assume that

$$
\begin{equation*}
\operatorname{rk}_{K_{v}} G_{1}=\operatorname{rk}_{K_{v}} G_{2} \text { for all } v \in V^{K} \tag{25}
\end{equation*}
$$

hence $L_{1}=L_{2}=$ : $L$. In each of the following situations:
(1) $G_{1}$ and $G_{2}$ are inner forms,
(2) $G_{1}$ and $G_{2}$ are outer forms, and one of them is represented by $\operatorname{SU}(D, \tau)$, where $D$ is a central division algebra over $L$ with an involution $\tau$ of the second kind that restricts to the nontrivial automorphism $\sigma$ of $L / K$ (then both groups are of this form),
the groups $G_{1}$ and $G_{2}$ have equivalent systems of maximal $K$-tori.

Proof. (1): We have $G_{i}=\mathrm{SL}_{1, A_{i}}$ where $A_{i}$ is a central simple algebra over $K$ of dimension $(n+1)^{2}$, and as in the proof of Lemma 6.2, it is enough to show that a commutative étale $(n+1)$-dimensional $K$-algebra $E$ embeds in $A_{1}$ if and only if it embeds in $A_{2}$. For $v \in V^{K}$, we can write

$$
A_{i} \otimes_{K} K_{v}=M_{d_{i}^{(v)}}\left(\Delta_{i}^{(v)}\right)
$$

where $\Delta_{i}^{(v)}$ is a central division algebra over $K_{v}$, of degree $m_{i}^{(v)}$. As in the proof of Lemma 6.2, we conclude that (25) implies $m_{1}^{(v)}=m_{2}^{(v)}$. On the other hand, it is wellknown (cf. [14], Propositions 2.6 and 2.7) that an $(n+1)$-dimensional commutative étale $K$-algebra $E=\prod_{j=1}^{s} E^{(j)}$, where $E^{(j)} / K$ is a finite (separable) field extension, embeds in $A_{i}$ if and only if for each $j \leqslant s$ and all $v \in V^{K}$, the local degree [ $E_{w}^{(j)}: K_{v}$ ] is divisible by $m_{i}^{(v)}$ for all extensions $w \mid v$, and the required fact follows.
(2): We have $G_{i}=\operatorname{SU}\left(D_{i}, \tau_{i}\right)$, where $D_{i}$ is a central simple algebra of degree $m=$ $n+1$ over $L$ with an involution $\tau_{i}$ such that $\tau_{i} \mid L=\sigma$. Assume that $D_{1}$ is a division algebra. Then it follows from the Albert-Hasse-Brauer-Noether Theorem that $m=$ $\operatorname{lcm}_{w \in V^{L}}\left(m_{1}^{(w)}\right)$, where for $w \in V^{L}, D_{i} \otimes_{L} L_{w}=M_{d_{i}^{(w)}}\left(\Delta_{i}^{(w)}\right)$ with $\Delta_{i}^{(w)}$ a central division algebra over $L_{w}$ of degree $m_{i}^{(w)}$. For $j=1,2$, set

$$
V_{j}^{L}=\left\{w \in V^{L} \mid\left[L_{w}: K_{v}\right]=j \text { where } w \mid v\right\} .
$$

It is well-known that $m_{i}^{(w)}=1$ for $w \in V_{2}^{L}$, so

$$
m=\operatorname{lcm}_{w \in V_{1}^{L}}\left(m_{1}^{(w)}\right)
$$

On the other hand, for $w \in V_{1}^{L}$ we have $G_{i} \simeq \mathrm{SL}_{d_{i}^{(w)}, \Delta_{i}^{(w)}}$ over $K_{v}=L_{w}$, hence $\mathrm{rk}_{K_{v}} G_{i}=d_{i}^{(w)}-1$. Thus, (25) implies that $m_{1}^{(w)}=m_{2}^{(w)}$ for all $w \in V_{1}^{L}$, and therefore

$$
m=\operatorname{lcm}_{w \in V_{1}^{L}}\left(m_{2}^{(w)}\right) .
$$

It follows that $D_{2}$ is a division algebra, as required.
Next, since any maximal $K$-torus of $G_{i}$ is of the form $\mathrm{R}_{E / K}\left(\mathrm{GL}_{1}\right) \cap G_{i}$ for some $m$-dimensional commutative étale $L$-algebra invariant under $\tau_{i}$ (cf. [14], Proposition 2.3 ), it is enough to show that for an $m$-dimensional commutative étale $L$-algebra $E$ with an involutive automorphism $\tau$ such that $\tau \mid L=\sigma$, the existence of an embedding $\iota_{1}:(E, \tau) \hookrightarrow\left(D_{1}, \tau_{1}\right)$ as $L$-algebras with involutions is equivalent to the existence of an embedding $\iota_{2}:(E, \tau) \hookrightarrow\left(D_{2}, \tau_{2}\right)$. Since $D_{1}$ is a division algebra, the existence of $\iota_{1}$ implies that $E / L$ is a field extension, and then by Theorem 4.1 of [14], the existence of $\iota_{2}$ is equivalent to the existence of an $\left(L \otimes_{K} K_{v}\right)$-embedding

$$
\iota_{2}^{(v)}:\left(E \otimes_{K} K_{v}, \tau \otimes \operatorname{id}_{K_{v}}\right) \hookrightarrow\left(D_{2} \otimes_{K} K_{v}, \tau_{2} \otimes \operatorname{id}_{K_{v}}\right)
$$

for all $v \in V^{K}$. If $v \in V^{K}$ has two extensions $w^{\prime}, w^{\prime \prime} \in V_{1}^{L}$, then $m_{i}^{\left(w^{\prime}\right)}=m_{i}^{\left(w^{\prime \prime}\right)}=$ : $m_{i}^{(v)}$ and the necessary and sufficient condition for the existence of $\iota_{i}^{(v)}$ is that for any extension $u$ of $v$ to $E$, the local degree $\left[E_{u}: K_{v}\right]$ is divisible by $m_{i}^{(v)}$ (cf. Proposition
A. 3 in [8]). Therefore, since $m_{1}^{(v)}=m_{2}^{(v)}$, the existence of $\iota_{1}^{(v)}$ implies that of $\iota_{2}^{(v)}$. If $v$ has only one extension $w$ to $L$, then $w \in V_{2}^{L}$ and

$$
\left(D_{i} \otimes_{K} K_{v}, \tau_{i} \otimes \operatorname{id}_{K_{v}}\right) \simeq\left(M_{m}\left(L_{w}\right), \theta_{i}\right)
$$

with $\theta_{i}$ given by $\theta\left(\left(x_{s t}\right)\right)=a_{i}^{-1}\left(\bar{x}_{t s}\right) a_{i}$ where $x \mapsto \bar{x}$ denotes the nontrivial automorphism of $L_{w} / K_{v}$ and $a_{i}$ is a Hermitian matrix. Furthermore, $\mathrm{rk}_{K_{v}} G_{i}$ equals the Witt index $i\left(h_{i}\right)$ of the Hermitian form $h_{i}$ with matrix $a_{i}$. Then (25) yields that $i\left(h_{1}\right)=i\left(h_{2}\right)$ which as we have seen in the proof of Lemma 6.2(i) implies that $h_{1}$ and $h_{2}$ are similar. Hence,

$$
\left(D_{1} \otimes_{K} K_{v}, \tau_{1} \otimes \operatorname{id}_{K_{v}}\right) \simeq\left(D_{2} \otimes_{K} K_{v}, \tau_{2} \otimes \mathrm{id}_{K_{v}}\right)
$$

and therefore again the existence of $\iota_{1}^{(v)}$ implies the existence of $\iota_{2}^{(v)}$.
Finally, since $D_{2}$ is also a division algebra, we can use the above argument to conclude that $\left(D_{1}, \tau_{1}\right)$ and $\left(D_{2}, \tau_{2}\right)$ in fact have the same $m$-dimensional commutative étale $L$ subalgebras invariant under the involutions as claimed.

Remark 6.4. (1) We have already noted prior to Proposition 6.3 that the assumption (2) of Theorem 6.1 is not needed in its statement. So, it is worth mentioning that assumption (1) in this situation is in fact satisfied automatically: for groups of outer type $A_{n}$ this follows from Corollary 4.5 in [14], while for groups of inner type $A_{n}$ it is much simpler, viz. in the notation used in the proof of Proposition 6.3(1), one shows that the algebras $A_{1}$ and $A_{2}$ contain a common field extension of $K$ of degree $(n+1)$. This can also be established for groups of type $D_{n}$ with $n$ odd using Proposition A of (14.
(2) We would like to clarify that assumption (2) of Theorem 6.1 is only needed to conclude that $\amalg^{2}\left(T_{1}\right)$ is trivial for any maximal $K$-torus $T_{1}$ of $G_{1}$. However, this fact holds for any maximal $K$-torus in a connected absolutely almost simple simply connected algebraic $K$-group of inner type $A_{n}$ unconditionally, cf. Remark 9.13 in [13]. So, the proof of Theorem 6.1 actually yields part (1) of Proposition 6.3.

Corollary 6.5. Let $G_{1}$ and $G_{2}$ be two connected absolutely almost simple simply connected algebraic groups of type $A_{p-1}$, where $p$ is a prime, over a number field $K$. Assume that (25) holds and that $L_{1}=L_{2}=: L$. Then $G_{1}$ and $G_{2}$ have equivalent systems of maximal $K$-tori.

Indeed, if $G_{1}$ and $G_{2}$ are inner forms (in particular, if $p=2$ ) then our assertion immediately follows from Proposition 6.3(1). Furthermore, if one of the groups is of the form $\operatorname{SU}(D, \tau)$ where $D$ is a central division algebra over $L$ of degree $p$ then we can use Proposition 6.3(2). It remains to consider the case where $G_{i}=\operatorname{SU}\left(L, h_{i}\right)$ with $h_{i}$ a nondegenerate hermitian form on $L^{p}$ for $i=1,2$. Then the proof of Lemma 6.2(i) shows that $h_{1}$ and $h_{2}$ are similar over $L_{w}$ for all $w \in V_{2}^{L}$. But then $h_{1}$ and $h_{2}$ are similar, i.e., $G_{1} \simeq G_{2}$ over $K$ and there is nothing to prove.

Here is a companion to Theorem 5.3 for groups of types $A, D$ and $E_{6}$.
Theorem 6.6. Let $G_{1}$ and $G_{2}$ be two connected absolutely almost simple algebraic groups of the same Killing-Cartan type which is one of the following: $A_{n}, D_{2 n+1}(n>1)$
or $E_{6}$ defined over a field $F$ of characteristic zero, and let $\Gamma_{i} \subset G_{i}(F)$ be a Zariskidense $\left(\mathscr{G}_{i}, K_{i}, S_{i}\right)$-arithmetic subgroup. Assume that for at least one $i \in\{1,2\}$ there exists $v_{0}^{(i)} \in V^{K_{i}}$ such that $\mathscr{G}_{i}$ is anisotropic over $\left(K_{i}\right)_{v_{0}^{(i)}}$. Then either condition $\left(C_{i}\right)$ holds for some $i \in\{1,2\}$, or $K_{1}=K_{2}=: K$ and the groups $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ have equivalent systems of maximal $K$-tori.
(We note that if $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ have equivalent systems of maximal $K$-tori then $\left(C_{i}\right)$ can hold only if $S_{1} \neq S_{2}$.)

Proof. We can obviously assume that for $i=1,2$, the group $G_{i}$ is adjoint and $\Gamma_{i} \subset$ $\mathscr{G}_{i}\left(K_{i}\right)$. According to Theorem [5.1, if neither $\left(C_{1}\right)$ nor $\left(C_{2}\right)$ hold, then we have

$$
K_{1}=K_{2}=: K, \quad L_{1}=L_{2}=: L, \quad S_{1}=S_{2}=: S
$$

and

$$
\mathrm{rk}_{K_{v}} \mathscr{G}_{1}=\mathrm{rk}_{K_{v}} \mathscr{G}_{2} \text { for all } v \in V^{K} .
$$

Furthermore, there exists $m \geqslant 1$ such that any $m$ multiplicatively independent semisimple elements $\gamma_{1}, \ldots, \gamma_{m} \in \Gamma_{1}$ are necessarily weakly contained in $\Gamma_{2}$. Arguing as in the proof of Theorem 5.1, we can find $m$ multiplicatively independent elements $\gamma_{1}, \ldots, \gamma_{m} \in \Gamma_{1}$ so that the corresponding tori $T_{i}=Z_{\mathscr{G}_{1}}\left(\gamma_{i}\right)^{\circ}$ satisfy the following:

- $\theta_{T_{i}}\left(\operatorname{Gal}\left(L_{T_{i}} / L\right)\right)=W\left(\mathscr{G}_{1}, T_{i}\right)$;
- $\operatorname{rk}_{K_{v}} T_{i}=\operatorname{rk}_{K_{v}} \mathscr{G}_{1}$ for all $v \in S$.

Then the fact that $\gamma_{1}, \ldots, \gamma_{m}$ are weakly contained in $\Gamma_{2}$ would imply that there exists a maximal $K$-torus $T_{2}^{0}$ of $\mathscr{G}_{2}$ and an $i \leqslant m$ such that there is a $K$-isogeny $T_{2}^{0} \rightarrow$ $T_{1}^{0}:=T_{i}$. Since the common type of $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ is different from $B_{2}=C_{2}, F_{4}$ and $G_{2}$, it follows from Lemma 4.3 and Remark 4.4 in 13 that one can scale the isogeny so that it induces an isomorphism between the root systems $\Phi\left(\mathscr{G}_{1}, T_{1}^{0}\right)$ and $\Phi\left(\mathscr{G}_{2}, T_{2}^{0}\right)$, and therefore extends to a $\bar{K}$-isomorphism $\mathscr{G}_{1} \rightarrow \mathscr{G}_{2}$ as these groups are adjoint. Passing to the simply connected groups $\widetilde{\mathscr{G}}_{1}$ and $\widetilde{\mathscr{G}}_{2}$ and the corresponding tori $\widetilde{T}_{1}^{0}$ and $\widetilde{T}_{2}^{0}$, we see that there exists a $K$-isomorphism $\widetilde{T}_{1}^{0} \rightarrow \widetilde{T}_{2}^{0}$ that extends to a $\bar{K}$-isomorphism $\widetilde{\mathscr{G}}_{1} \rightarrow \widetilde{\mathscr{G}}_{2}$. Note that by our construction we have $\mathrm{rk}_{K_{v}} T_{i}^{0}=\mathrm{rk}_{K_{v}} \mathscr{G}_{i}$ for $i=1,2$ and all real places $v$ of $K$. In view of our assumptions, we can invoke Theorem 6.1 to conclude that $\widetilde{\mathscr{G}}_{1}$ and $\widetilde{\mathscr{G}}_{2}$ have equivalent systems of maximal $K$-tori, and then the same remains true for $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$.

It follows from Proposition 6.3 and Corollary 6.5 that the assertion of Theorem 6.6 remains valid without the assumption that there be $v_{0}^{(i)} \in V^{K_{i}}$ such that $\mathscr{G}_{i}$ is $\left(K_{i}\right)_{v_{0}^{(i)} \text { - }}$ anisotropic for groups of type $A_{n}$ in the following three situations: (1) one of the $\mathscr{G}_{i}$ 's is an inner form; (2) the simply connected cover of one of the $\mathscr{C}_{i}$ 's is isomorphic to $\mathrm{SU}(D, \tau)$ where $D$ is a central division algebra over $L$ with an involution $\tau$ of the second kind that restricts to the nontrivial automorphism of $L / K$; (3) $n=p-1$ where $p$ is a prime.

## 7. Fields generated By the lengths of closed geodesics

Let $G$ be an absolutely simple adjoint algebraic $\mathbb{R}$-group such that $\mathcal{G}:=G(\mathbb{R})$ is noncompact. Pick a maximal compact subgroup $\mathcal{K}$ of $\mathcal{G}$, and let $\mathfrak{X}=\mathcal{K} \backslash \mathcal{G}$ denote the corresponding symmetric space considered as a Riemannian manifold with the metric induced by the Killing form. Given a discrete torsion-free subgroup $\Gamma \subset \mathcal{G}$, we consider the associated locally symmetric space $\mathfrak{X}_{\Gamma}:=\mathfrak{X} / \Gamma$. It was shown in [13], 8.4, that every (nontrivial) semisimple element $\gamma \in \Gamma$ gives rise to a closed geodesic $c_{\gamma}$ in $\mathfrak{X}_{\Gamma}$, and conversely, every closed geodesic can be obtained that way. Moreover, the length $\ell\left(c_{\gamma}\right)$ can be written in the form $\left(1 / n_{\gamma}\right) \cdot \lambda_{\Gamma}(\gamma)$ where $n_{\gamma} \geqslant 1$ is an integer and

$$
\begin{equation*}
\lambda_{\Gamma}(\gamma)=\left(\sum_{\alpha}(\log |\alpha(\gamma)|)^{2}\right)^{1 / 2} \tag{26}
\end{equation*}
$$

where the summation is over all roots $\alpha$ of $G$ with respect to an arbitrary maximal $\mathbb{R}$-torus $T$ containing $\gamma$ (Proposition 8.5 of [13]). In particular, for the set $L\left(\mathfrak{X}_{\Gamma}\right)$ of lengths of all closed geodesics in $\mathfrak{X}_{\Gamma}$ we have

$$
\mathbb{Q} \cdot L\left(\mathfrak{X}_{\Gamma}\right)=\mathbb{Q} \cdot\left\{\lambda_{\Gamma}(\gamma) \mid \gamma \in \Gamma \text { nontrivial semisimple }\right\},
$$

and the subfield of $\mathbb{R}$ generated by $L\left(\mathfrak{X}_{\Gamma}\right)$ coincides with the subfield generated by the values $\lambda_{\Gamma}(\gamma)$ for all semisimple $\gamma \in \Gamma$.

Now, let $G_{1}$ and $G_{2}$ be two absolutely simple adjoint algebraic $\mathbb{R}$-groups such that the group $\mathcal{G}_{i}:=G_{i}(\mathbb{R})$ is noncompact for both $i=1,2$. For each $i \in\{1,2\}$, we pick a maximal compact subgroup $\mathcal{K}_{i}$ of $\mathcal{G}_{i}:=G_{i}(\mathbb{R})$ and consider the symmetric space $\mathfrak{X}_{i}=\mathcal{K}_{i} \backslash \mathcal{G}_{i}$. Furthermore, given a discrete torsion-free Zariski-dense subgroup $\Gamma_{i}$ of $\mathcal{G}_{i}$, we let $\mathfrak{X}_{\Gamma_{i}}:=\mathfrak{X}_{i} / \Gamma_{i}$ denote the associated locally symmetric space. As above, for $i=1,2$, we let $w_{i}$ denote the order of the Weyl group of $G_{i}$ with respect to a maximal torus, and let $K_{\Gamma_{i}}$ be the field of definition of $\Gamma_{i}$, i.e. the subfield of $\mathbb{R}$ generated by the traces $\operatorname{Tr} \operatorname{Ad} \gamma$ for $\gamma \in \Gamma_{i}$. In this section, we will focus our attention on the fields $\mathscr{F}_{i}$ generated by the set $L\left(\mathfrak{X}_{\Gamma_{i}}\right)$, for $i=1,2$.

The results of this section depend on the truth of Schanuel's conjecture from transcendental number theory (hence they are conditional). For the reader's convenience we recall its statement (cf. [1], [2], p. 120).
Schanuel's conjecture. If $z_{1}, \ldots, z_{n} \in \mathbb{C}$ are linearly independent over $\mathbb{Q}$, then the transcendence degree (over $\mathbb{Q})$ of the field generated by

$$
z_{1}, \ldots, z_{n} ; e^{z_{1}}, \ldots, e^{z_{n}}
$$

$i s \geqslant n$.
Assuming Schanuel's conjecture and developing the techniques of [11], we prove the following proposition which enables us to connect the results of the previous sections to some geometric problems involving the sets $L\left(\mathfrak{X}_{\Gamma_{i}}\right)$ and the fields $\mathscr{F}_{i}$.

Proposition 7.1. Let $\mathscr{K} \subset \mathbb{R}$ be a subfield of finite transcendence degree d over $\mathbb{Q}$, let $G_{1}$ and $G_{2}$ be semisimple $\mathscr{K}$-groups, and for $i \in\{1,2\}$, let $\Gamma_{i} \subset G_{i}(\mathscr{K}) \subset G_{i}(\mathbb{R})$ be a discrete Zariski-dense torsion-free subgroup. As above, for $i=1,2$, let $\mathscr{F}_{i}$ be the subfield
of $\mathbb{R}$ generated by the $\lambda_{\Gamma_{i}}(\gamma)$ for all nontrivial semi-simple $\gamma \in \Gamma_{i}$, where $\lambda_{\Gamma_{i}}(\gamma)$ is given by equation (26) for $G=G_{i}$. If nontrivial semisimple elements $\gamma_{1}, \ldots, \gamma_{m} \in \Gamma_{1}$ are multiplicatively independent and are not weakly contained in $\Gamma_{2}$, then the transcendence degree of $\mathscr{F}_{2}\left(\lambda_{\Gamma_{i}}\left(\gamma_{1}\right), \ldots, \lambda_{\Gamma_{i}}\left(\gamma_{m}\right)\right)$ over $\mathscr{F}_{2}$ is $\geqslant m-d$.

Proof. We can assume that $m>d$ as otherwise there is nothing to prove. It was shown in [13] (see the remark after Proposition 8.5) that for $i=1,2$ and any nontrivial semisimple element $\gamma \in \Gamma_{i}$, the value $\lambda_{\Gamma_{i}}(\gamma)^{2}$, where $\lambda_{\Gamma_{i}}(\gamma)$ is provided by (26), can be written in the form

$$
\begin{equation*}
\lambda_{\Gamma_{i}}(\gamma)^{2}=\sum_{k=1}^{p} s_{k}\left(\log \chi_{k}(\gamma)\right)^{2}, \tag{27}
\end{equation*}
$$

where $\chi_{1}, \ldots, \chi_{p}$ are some positive characters of a maximal $\mathbb{R}$-torus $T$ of $G_{i}$ containing $\gamma$, and $s_{1}, \ldots, s_{p}$ are some positive rational numbers. Furthermore, we note that if $\gamma \in \Gamma_{i}$ is a semisimple element $\neq 1$ and $T$ is a maximal $\mathbb{R}$-torus of $G_{i}$ containing $\gamma$ then the condition $|\alpha(\gamma)|=1$ for all roots $\alpha$ of $G_{i}$ with respect to $T$ would imply that the nontrivial subgroup $\langle\gamma\rangle$ is discrete and relatively compact, hence finite. This is impossible as $\Gamma_{i}$ is torsion-free, so we conclude from (26) that $\lambda_{\Gamma_{i}}(\gamma)>0$ for any nontrivial $\gamma \in \Gamma_{i}$. Thus, assuming that $\gamma \in \Gamma_{i}$ is nontrivial and renumbering the characters in (27), we can arrange so that

$$
a_{\gamma, 1}=\log \chi_{1}(\gamma), \ldots, a_{\gamma, d_{\gamma}}=\log \chi_{d_{\gamma}}(\gamma) \text { with } d_{\gamma} \geqslant 1,
$$

form a basis of the $\mathbb{Q}$-vector subspace of $\mathbb{R}$ spanned by $\log \chi_{1}(\gamma), \ldots, \log \chi_{p}(\gamma)$. Then we can write $\lambda_{\Gamma_{i}}(\gamma)^{2}=q_{\gamma}\left(a_{\gamma, 1}, \ldots, a_{\gamma, d_{\gamma}}\right)$ where $q_{\gamma}\left(t_{1}, \ldots, t_{d_{\gamma}}\right)$ is a nontrivial rational quadratic form. Thus, for any nontrivial semisimple $\gamma \in \Gamma_{i}$ there exists a finite set $A_{\gamma}=\left\{a_{\gamma, 1}, \ldots, a_{\gamma, d_{\gamma}}\right\}$, with $d_{\gamma} \geqslant 1$, of real numbers linearly independent over $\mathbb{Q}$, each of which is the logarithm of the value of a positive character on $\gamma$, such that

$$
\lambda_{\Gamma_{i}}(\gamma)^{2}=q_{\gamma}\left(a_{\gamma, 1}, \ldots, a_{\gamma, d_{\gamma}}\right),
$$

where $q_{\gamma}\left(t_{1}, \ldots, t_{d_{\gamma}}\right)$ is a nonzero rational quadratic form. We fix such $A_{\gamma}$ and $q_{\gamma}$ for each nontrivial semi-simple $\gamma \in \Gamma_{i}$, where $i=1,2$, for the remainder of the argument. Let $\mathscr{M}_{i}$ be the subfield of $\mathbb{R}$ generated by the values $\lambda_{\Gamma_{i}}(\gamma)^{2}=q_{\gamma}\left(a_{\gamma, 1}, \ldots, a_{\gamma, d_{\gamma}}\right)$ for all nontrivial semisimple $\gamma \in \Gamma_{i}$.

Now, suppose $\gamma_{1}, \ldots, \gamma_{m} \in \Gamma_{1}$ are as in the statement of the proposition. It is enough to show that for any finitely generated subfield $\mathscr{M}_{2}^{\prime} \subset \mathscr{M}_{2}$, we have

$$
\operatorname{tr} . \operatorname{deg}_{\mathscr{M}_{2}^{\prime}} \mathscr{M}_{2}^{\prime}\left(\lambda_{\Gamma_{i}}\left(\gamma_{1}\right)^{2}, \ldots, \lambda_{\Gamma_{i}}\left(\gamma_{m}\right)^{2}\right) \geqslant m-d .
$$

Indeed, this would imply that $\operatorname{tr} . \operatorname{deg}_{\mathscr{M}_{2}} \mathscr{M}_{2}\left(\lambda_{\Gamma_{i}}\left(\gamma_{1}\right)^{2}, \ldots, \lambda_{\Gamma_{i}}\left(\gamma_{m}\right)^{2}\right)$, and hence (as $\mathscr{F}_{2} / \mathscr{M}_{2}$ is algebraic) tr. $\operatorname{deg}_{\mathscr{F}_{2}} \mathscr{F}_{2}\left(\lambda_{\Gamma_{i}}\left(\gamma_{1}\right)^{2}, \ldots, \lambda_{\Gamma_{i}}\left(\gamma_{m}\right)^{2}\right)$ is $\geqslant m-d$, yielding the proposition. We now note that any finitely generated subfield $\mathscr{M}_{2}^{\prime} \subset \mathscr{M}_{2}$ is contained in a subfield of the form $\mathscr{P}_{\Theta_{2}}$ for some finite set $\Theta_{2}=\left\{\gamma_{1}^{(2)}, \ldots, \gamma_{m_{2}}^{(2)}\right\}$ of nontrivial semisimple elements of $\Gamma_{2}$, which by definition is generated by $\bigcup_{k=1}^{m_{2}} A_{\gamma_{k}^{(2)}}$. So, it is enough to prove that if $\gamma_{1}, \ldots, \gamma_{m} \in \Gamma_{1}$ are as in the statement of the proposition then
for any finite set $\Theta_{2}$ of nontrivial semi-simple elements of $\Gamma_{2}$ we have

$$
\begin{equation*}
\operatorname{tr} . \operatorname{deg}_{\mathscr{P}_{\Theta_{2}}} \mathscr{P}_{\Theta_{2}}\left(\lambda_{\Gamma_{i}}\left(\gamma_{1}\right), \ldots, \lambda_{\Gamma_{i}}\left(\gamma_{m}\right)\right) \geqslant m-d . \tag{28}
\end{equation*}
$$

Since the elements $\gamma_{1}, \ldots, \gamma_{m}$ are multiplicatively independent, the elements of

$$
A=\bigcup_{j=1}^{m} A_{\gamma_{j}}
$$

are linearly independent (over $\mathbb{Q}$ ). Let $B$ be a maximal linearly independent (over $\mathbb{Q}$ ) subset of $\bigcup_{k=1}^{m_{2}} A_{\gamma_{k}^{(2)}}$. Since $\gamma_{1}, \ldots, \gamma_{m}$ are not weakly contained in $\Gamma_{2}$, the elements of $A \cup B$ are linearly independent over $\mathbb{Q}$. Let $\alpha=|A|$ and $\beta=|B|$. Then by Schanuel's conjecture, the transcendence degree over $\mathbb{Q}$ of the field generated by

$$
A \cup B \cup \widetilde{A} \cup \widetilde{B}, \text { where } \widetilde{A}=\left\{e^{s} \mid s \in A\right\} \text { and } \widetilde{B}=\left\{e^{s} \mid s \in B\right\},
$$

is $\geqslant \alpha+\beta$. But the set $\widetilde{A} \cup \widetilde{B}$ consists of the values of certain characters on certain semi-simple elements lying in $\Gamma_{i} \subset G_{i}(\mathscr{K})$, and therefore is contained in $\overline{\mathscr{K}}$. It follows that the transcendence degree over $\mathbb{Q}$ of the field generated by $\widetilde{A} \cup \widetilde{B}$ is $\leqslant d$, and therefore the transcendence degree of the field generated by $A \cup B$ is $\geqslant \alpha+\beta-d$. So,

$$
\begin{gathered}
\operatorname{tr} . \operatorname{deg}_{\mathbb{Q}(B)} \mathbb{Q}(A \cup B)=\operatorname{tr} \cdot \operatorname{deg}_{\mathbb{Q}} \mathbb{Q}(A \cup B)-\operatorname{tr} \cdot \operatorname{deg}_{\mathbb{Q}} \mathbb{Q}(B) \geqslant \\
\geqslant(\alpha+\beta-d)-\beta=\alpha-d .
\end{gathered}
$$

Thus, there exists a subset $C \subset A$ of cardinality $\leqslant d$ such that the elements of $A \backslash C$ are algebraically independent over $\mathbb{Q}(B)$. Since $C$ intersects at most $d$ of the sets $A_{\gamma_{j}}$, $j \leqslant m$, we see that after renumbering, we can assume that the elements of

$$
D=\bigcup_{j=1}^{m-d} A_{\gamma_{j}}
$$

are algebraically independent over $\mathbb{Q}(B)$. Since $\mathbb{Q}(B)$ coincides with $\mathscr{P}_{\Theta_{2}}$, (28) follows from the following simple lemma.

Lemma 7.2. Let $F$ be a field, and let $E=F\left(t_{1}, \ldots, t_{n}\right)$, where $t_{1}, \ldots, t_{n}$ are algebraically independent over $F$. Let

$$
\{1,2, \ldots, n\}=I_{1} \cup \cdots \cup I_{s}
$$

be an arbitrary partition, and let $E_{j}$ be the field generated over $F$ by the $t_{i}$ for $i \in I_{j}$. For each $j \in\{1, \ldots, s\}$, pick $f_{j} \in E_{j} \backslash F$. Then

$$
\operatorname{tr} . \operatorname{deg}_{F} F\left(f_{1}, \ldots, f_{s}\right)=s
$$

Now if property $\left(C_{i}\right)$ holds for $i=1$ or 2 , then Proposition 7.1 implies the following at once.

Corollary 7.3. Notations and assumptions are as in Proposition 7.1, assume that condition $\left(C_{i}\right)$ holds for either $i=1$ or 2 . Then the transcendence degree of $\mathscr{F}_{1} \mathscr{F}_{2}$ over $\mathscr{F}_{3-i}$ is infinite, i.e. condition $\left(T_{i}\right)$ (of the introduction) holds.

Combining the corollary with Theorem 4.2, we obtain Theorem 1 (of the introduction). This theorem has the following important consequence. In [13], §8, we had to single out the following exceptional case
$(\mathcal{E})$ One of the locally symmetric spaces, say, $\mathfrak{X}_{\Gamma_{1}}$, is 2-dimensional and the corresponding discrete subgroup $\Gamma_{1}$ cannot be conjugated into $\mathrm{PGL}_{2}(K)$, for any number field $K \subset \mathbb{R}$, and the other space, $\mathfrak{X}_{\Gamma_{2}}$, has dimension $>2$,
which was then excluded in some of our results. Theorem 1(1) shows that the locally symmetric spaces as in $(\mathcal{E})$ can never be length-commensurable (assuming Schanuel's conjecture), and therefore all our results are in fact valid without the exclusion of case $(\mathcal{E})$.

As we mentioned in the introduction, much more precise results are available when the groups $\Gamma_{1}$ and $\Gamma_{2}$ are arithmetic. In this section we will prove Theorems 2 and 3 that treat the case where $G_{1}$ and $G_{2}$ are of the same Cartan-Killing type, and postpone the proof of Theorem 4, where one of the group is of type $B_{n}$ and the other is of type $C_{n}$ for some $n \geqslant 3$, until the next section. In fact, Theorem 2 follows immediately from Corollary 7.3 and Theorem 5.3. It should be noted that while Theorem 2 asserts that conditions $\left(T_{i}\right)$ and $\left(N_{i}\right)$ hold for at least one $i \in\{1,2\}$, these may not hold for both $i$.
Example 7.4. Let $D_{1}$ and $D_{2}$ be the quaternion algebras over $\mathbb{Q}$ with the sets of ramified places $\{2,3\}$ and $\{2,3,5,7\}$, respectively. Set $G_{i}=\mathrm{PSL}_{1, D_{i}}$, and let $\Gamma_{i}$ be a torsion-free subgroup of $G_{i}(\mathbb{Q})$, for $i=1,2$. Over $\mathbb{R}$, both $G_{1}$ and $G_{2}$ are isomorphic to $G=\mathrm{PSL}_{2}$, so $\Gamma_{1}$ and $\Gamma_{2}$ can be viewed as arithmetic subgroups of $\mathcal{G}=G(\mathbb{R})$. The symmetric space $\mathfrak{X}$ associated with $\mathcal{G}$ is the hyperbolic plane $\mathbb{H}^{2}$, so the corresponding locally symmetric spaces $\mathfrak{X}_{\Gamma_{1}}$ and $\mathfrak{X}_{\Gamma_{2}}$ are arithmetically defined hyperbolic 2-manifolds that are not commensurable as the groups $G_{1}$ and $G_{2}$ are not $\mathbb{Q}$-isomorphic. At the same time, our choice of $D_{1}$ and $D_{2}$ implies that every maximal subfield of $D_{2}$ is isomorphic to a maximal subfield of $D_{1}$ which entails that $\mathbb{Q} \cdot L\left(\mathfrak{X}_{\Gamma_{2}}\right) \subset \mathbb{Q} \cdot L\left(\mathfrak{X}_{\Gamma_{1}}\right)$, hence $\mathscr{F}_{2} \subset \mathscr{F}_{1}$. Thus, $\mathscr{F}_{1} \mathscr{F}_{2}=\mathscr{F}_{1}$, so ( $T_{1}$ ) does not hold (although ( $T_{2}$ ) does hold).

Next, we will derive Theorem 3 from Theorem 6.6, Let $\Gamma_{i}$ be $\left(\mathscr{G}_{i}, K_{i}\right)$-arithmetic. Assume that $\left(T_{i}\right)$, hence $\left(C_{i}\right)$, does not hold for either $i=1$ or 2 . Then by Theorem 6.6 we necessarily have $K_{1}=K_{2}=: K$, and the groups $\mathscr{G}_{1}, \mathscr{G}_{2}$ have equivalent systems of maximal $K$-tori. By the assumption made in Theorem $3, K \neq \mathbb{Q}$. The field $K$ has the real place associated with the identity embedding $K \hookrightarrow \mathbb{R}$ but since $K \neq \mathbb{Q}$, it necessarily has another archimedean place $v_{0}$, and the discreteness of $\Gamma_{i}$ implies that $\mathscr{G}_{i}$ is $K_{v_{0}}$-anisotropic. Thus, Theorem 6.6 applies to the effect that the groups $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ have equivalent systems of maximal $K$-tori. Then the fact that $\mathbb{Q} \cdot L\left(\mathfrak{X}_{\Gamma_{1}}\right)=\mathbb{Q} \cdot L\left(\mathfrak{X}_{\Gamma_{2}}\right)$ follows from the following.

Proposition 7.5. (cf. [13], Proposition 9.14) Let $G_{1}$ and $G_{2}$ be connected absolutely simple algebraic groups such that $\mathcal{G}_{i}=G_{i}(\mathbb{R})$ is noncompact for both $i=1,2$, and let $\mathfrak{X}_{i}$ be the symmetric space associated with $\mathcal{G}_{i}$. Furthermore, let $\Gamma_{i} \subset \mathcal{G}_{i}$ be a discrete torsion-free ( $\mathscr{G}_{i}, K$ )-arithmetic subgroup (where $K \subset \mathbb{R}$ is a number field), and $\mathfrak{X}_{\Gamma_{i}}=$ $\mathfrak{X} / \Gamma_{i}$ be the corresponding locally symmetric space for $i=1,2$. If $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ have equivalent systems of maximal $K$-tori, then $\mathfrak{X}_{\Gamma_{1}}$ and $\mathfrak{X}_{\Gamma_{2}}$ are length-commensurable.

This is essentially Proposition 9.14 of [13] except that here we require that the groups $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ have equivalent systems of maximal $K$-tori instead of the more technical requirement of having coherently equivalent systems of maximal $K$-tori used in [13]; this change however does not affect the proof.

The analysis of our argument in conjunction with Proposition 6.3 and Corollary 6.5 shows that the assertion of Theorem 3 remains valid without the assumption that $K_{\Gamma_{i}} \neq \mathbb{Q}$ at least in the following situations where $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are of type $A_{n}:(1)$ one of the $\mathscr{G}_{i}$ 's is an inner form; (2) one of the $\mathscr{G}_{i}$ 's is represented by $\operatorname{SU}(D, \tau)$ where $D$ is a central division algebra over $L$ with an involution $\tau$ of the second kind that restricts to the nontrivial automorphism of $L / K$; (3) $n=p-1$, where $p$ is a prime.

To illustrate our general results in a concrete geometric situation, we will now prove Corollary 1 of the introduction. The hyperbolic $d$-space $\mathbb{H}^{d}$ is the symmetric space of the group $G(d)=\operatorname{PSO}(d, 1)$. For $d \geqslant 2$, set $\ell=\left[\frac{d+1}{2}\right]$. Then for $d \neq 3, G(d)$ is an absolutely simple group of type $B_{\ell}$ if $d$ is even, and of type $D_{\ell}$ if $d$ is odd. Furthermore, the order $w(d)$ of the Weyl group of $G(d)$ is given by:

$$
w(d)=\left\{\begin{array}{ccc}
2^{\ell} \cdot \ell! & , & d \text { is even }, \\
2^{\ell-1} \cdot \ell! & , & d \text { is odd. }
\end{array}\right.
$$

One easily checks that $w(d)<w(d+1)$ for any $d \geqslant 2$, implying that $w\left(d_{1}\right)>w\left(d_{2}\right)$ whenever $d_{1}>d_{2}$. With these remarks, assertions (i) and (ii) follow from Theorem 1. Furthermore, using the above description of the Killing-Cartan type of $G(d)$ one easily derives assertions (iii) and (iv) from Theorems 2 and 3, respectively.

It follows from ([7], Theorem 5.7) that given a discrete torsion-free $\left(\mathscr{G}_{i}, K_{i}\right)$-arithmetic subgroup of $\mathcal{G}_{i}$, the compactness of the locally symmetric space $\mathfrak{X}_{\Gamma_{i}}$ is equivalent to the fact that $\mathscr{G}_{i}$ is $K_{i}$-anisotropic. Combining this with Theorem [5.8, we obtain Theorem 5.

Generalizing the notion of length-commensurability, one can define two Riemannian manifolds $M_{1}$ and $M_{2}$ to be "length-similar" if there exists a real number $\lambda>0$ such that

$$
\mathbb{Q} \cdot L\left(M_{2}\right)=\lambda \cdot \mathbb{Q} \cdot L\left(M_{1}\right) .
$$

One can show, however, that for arithmetically defined locally symmetric space, in most cases, this notion is redundant, viz. it coincides with the notion of length commensurability.

Corollary 7.6. Let $\Gamma_{i} \subset G_{i}(\mathbb{R})$ be a finitely generated Zariski-dense torsion-free subgroup. Assume that there exists $\lambda \in \mathbb{R}_{>0}$ such that

$$
\begin{equation*}
\mathbb{Q} \cdot L\left(\mathfrak{X}_{\Gamma_{1}}\right)=\lambda \cdot \mathbb{Q} \cdot L\left(\mathfrak{X}_{\Gamma_{2}}\right) . \tag{29}
\end{equation*}
$$

Then
(i) $w_{1}=w_{2}$ (hence either $G_{1}$ and $G_{2}$ are of the same type, or one of them is of type $B_{n}$ and the other of type $C_{n}$ for some $n \geqslant 3$ ) and $K_{\Gamma_{1}}=K_{\Gamma_{2}}=: K$.

Assume now that $\Gamma_{1}$ and $\Gamma_{2}$ are arithmetic. Then
(ii) $\mathrm{rk}_{\mathbb{R}} G_{1}=\operatorname{rk}_{\mathbb{R}} G_{2}$, and either $G_{1} \simeq G_{2}$ over $\mathbb{R}$, or one of the groups is of type $B_{n}$ and the other is of type $C_{n}$;
(iii) if $\Gamma_{i}$ is $\left(\mathcal{G}_{i}, K\right)$-arithmetic then $\mathrm{rk}_{K} \mathcal{G}_{1}=\mathrm{rk}_{K} \mathcal{G}_{2}$, and consequently, if one of the spaces is compact, the other must also be compact;
(iv) if $G_{1}$ and $G_{2}$ are of the same type which is different from $A_{n}, D_{2 n+1}(n>1)$ or $E_{6}$ then $\mathfrak{X}_{\Gamma_{1}}$ and $\mathfrak{X}_{\Gamma_{2}}$ are commensurable, hence length-commensurable;
(v) if $G_{1}$ and $G_{2}$ are of the same type which is one of the following: $A_{n}, D_{2 n+1}$ $(n>1)$ or $E_{6}$, then provided that $K_{\Gamma_{i}} \neq \mathbb{Q}$ for at least one $i \in\{1,2\}$, the spaces $\mathfrak{X}_{\Gamma_{1}}$ and $\mathfrak{X}_{\Gamma_{2}}$ are length-commensurable (although not necessarily commensurable).
Proof. If (29) holds then obviously ( $N_{i}$ ) cannot possibly hold for either $i=1$ or 2 . So, assertion (i) immediately follows from Theorem 1 . Now, if $\Gamma_{i}$ is $\left(\mathscr{G}_{i}, K\right)$-arithmetic, then neither $\left(N_{1}\right)$ nor $\left(N_{2}\right)$ holds, so neither $\left(C_{1}\right)$ nor $\left(C_{2}\right)$ can hold (cf. Corollary (7.3). So by Theorem 5.1 we have $\operatorname{rk}_{K_{v}} \mathscr{G}_{1}=\operatorname{rk}_{K_{v}} \mathscr{G}_{2}$ for all $v \in V^{K}$; in particular, $\mathrm{rk}_{\mathbb{R}} G_{1}=\mathrm{rk}_{\mathbb{R}} G_{2}$. Moreover, if $G_{1}$ and $G_{2}$ are of the same type then by Theorem 5.6, the Tits indices over $\mathbb{R}$ of $G_{1}$ and $G_{2}$ are isomorphic, and therefore $G_{1} \simeq G_{2}$, so assertion (ii) follows. Regarding (iii), the fact that $\operatorname{rk}_{K} \mathscr{G}_{1}=\operatorname{rk}_{K} \mathscr{G}_{2}$ is again a consequence of Theorem [5.6 in conjunction with Corollary [7.3; to relate this to the compactness of the corresponding locally symmetric spaces one argues as in the proof of Theorem 5 above. Finally, assertions (iv) and (v) follow from Theorems 2 and 3 respectively.

We note that assertions (iv) and (v) of the above corollary assert that if two arithmetically defined locally symmetric spaces of the same group are not length-commensurable then, under certain assumption, one cannot make them length-commensurable by scaling the metric on one of them (cf., however, Theorem 4).

## 8. Groups of types $B_{n}$ And $C_{n}$

The goal of this section is to prove Theorem 4 . Our argument will heavily rely on the results of [5]. Here is one of the main results.

Theorem 8.1. (5], Theorem 1.1) Let $G_{1}$ and $G_{2}$ be connected absolutely simple adjoint groups of types $B_{n}$ and $C_{n}(n \geqslant 3)$ respectively over a field $F$ of characteristic zero, and let $\Gamma_{i}$ be a Zariski-dense ( $\mathscr{G}_{i}, K, S$ )-arithmetic subgroup. Then $\Gamma_{1}$ and $\Gamma_{2}$ are weakly commensurable if and only if the following conditions hold:
(1) $\operatorname{rk}_{K_{v}} \mathscr{G}_{1}=\operatorname{rk}_{K_{v}} \mathscr{G}_{2}=n$ (in other words, $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are split over $K_{v}$ ) for all nonarchimedean $v \in V^{K}$, and
(2) $\operatorname{rk}_{K_{v}} \mathscr{G}_{1}=\operatorname{rk}_{K_{v}} \mathscr{G}_{2}=0$ or $n$ (i.e., both $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ are either anisotropic or split) for every archimedean $v \in V^{K}$.

Furthermore, it has been shown in [5] that the same two conditions precisely characterize the situations where $\mathscr{G}_{1}$ and $\mathscr{G}_{2}$ have the same isogeny classes of maximal $K$-tori, or, equivalently, $\mathscr{G}_{1}$ and $\widetilde{\mathscr{G}}_{2}$ (the universal cover of $\mathscr{G}_{2}$ ) have the same isomorphism classes of maximal $K$-tori. We need the following proposition which has actually been established in the course of the proof of Theorem 8.1 in (5).

Proposition 8.2. Notations and conventions be as in Theorem 8.1. Assume that $v_{0} \in V^{K}$ is such that the corresponding condition (1) or (2) fails. Then for at least one $i \in\{1,2\}$ there exists a $K_{v_{0}}$-isotropic maximal torus $T_{i}\left(v_{0}\right)$ of $\mathscr{G}_{i}$ such that no maximal $K$-torus $T_{i}$ of $\mathscr{G}_{i}$ satisfying
(i) $\theta_{T_{i}}\left(\operatorname{Gal}\left(K_{T_{i}} / K\right)\right)=W\left(\mathscr{G}_{i}, T_{i}\right)$,
(ii) $T_{i}$ is conjugate to $T_{i}\left(v_{0}\right)$ by an element of $\mathscr{G}_{i}\left(K_{v_{0}}\right)$
is $K$-isogeneous to a maximal $K$-torus of $\mathscr{G}_{3-i}$.
We will now use this proposition to prove the following.
Proposition 8.3. Notations and conventions be as in Theorem 8.1. Assume that there exists $v_{0} \in V^{K}$ such that the corresponding condition (1) or (2) fails. Then condition $\left(C_{i}\right)$ holds for at least one $i \in\{1,2\}$.

Proof. As $G_{1}$ and $G_{2}$ are adjoint, $\Gamma_{i} \subset \mathscr{G}_{i}(K)$ for $i=1,2$. Pick $i \in\{1,2\}$ and a maximal $K_{v_{0}}$-torus $T_{i}\left(v_{0}\right)$ of $\mathscr{G}_{i}$ as in Proposition [8.2, we will show that property $\left(C_{i}\right)$ holds for this $i$. Fix $m \geqslant 1$. Using Theorem 3.3, we can find maximal $K$-tori $T_{1}, \ldots, T_{m}$ of $\mathscr{G}_{i}$ that are independent over $K$ and satisfy the following conditions for each $j \leqslant m$ :

- $\theta_{T_{j}}\left(\operatorname{Gal}\left(K_{T_{j}} / K\right)\right)=W\left(\mathscr{G}_{i}, T_{j}\right)$,
- $T_{j}$ is conjugate to $T_{i}\left(v_{0}\right)$ by an element of $\mathscr{G}_{i}\left(K_{v_{0}}\right)$, and $\mathrm{rk}_{K_{v}} T_{j}=\mathrm{rk}_{K_{v}} \mathscr{G}_{i}$ for all $v \in S \backslash\left\{v_{0}\right\}$.
Since $T_{i}\left(v_{0}\right)$ is $K_{v}$-isotropic, we have $d_{T_{j}}(S):=\sum_{v \in S} \mathrm{rk}_{K_{v}} T_{j}>0$ no matter whether or not $v_{0}$ belongs to $S$. Besides, $T_{j}$ is automatically $K$-anisotropic, so it follows from Dirichlet's Theorem that one can pick an element of infinite order $\gamma_{j} \in \Gamma_{i} \cap T_{j}(K)$ for each $j \leqslant m$. These elements are multiplicatively independent by Lemma 2.1, so we only need to show that they are not weakly contained in $\Gamma_{3-i}$. However, by Theorem 2.3, a relation of weak containment would imply that $T_{j}$ for some $j \leqslant m$ would admit a $K$ isogeny onto a maximal $K$-torus $T^{(2)}$ of $\mathscr{G}_{2}$. However, this is impossible(cf. Proposition 8.2).

Let $G_{1}$ and $G_{2}$ be connected absolutely simple adjoint algebraic $\mathbb{R}$-groups of type $B_{n}$ and $C_{n}(n \geqslant 3)$ respectively, and let $\Gamma_{i}$ be a discrete torsion-free ( $\left.\mathscr{G}_{i}, K_{i}\right)$-arithmetic subgroup of $\mathcal{G}_{i}=G_{i}(\mathbb{R})$, for $i=1,2$. If $K_{1} \neq K_{2}$, then either condition ( $T_{1}$ ) or ( $T_{2}$ ) holds for the locally symmetric spaces $\mathfrak{X}_{\Gamma_{1}}$ and $\mathfrak{X}_{\Gamma_{2}}$ by Theorem 1 . So, let us assume that $K_{1}=K_{2}=: K$. If there exists $v_{0} \in V^{K}$ such that the corresponding condition (1) or (2) of Theorem 8.1 fails, then by Proposition 8.3 the groups $\Gamma_{1}$ and $\Gamma_{2}$ satisfy $\left(C_{i}\right)$ for at least one $i \in\{1,2\}$, and then $\left(T_{i}\right)$ holds for the same $i$ (cf. Corollary [7.3). So, to complete the proof of Theorem 4, it remains to be shown that if conditions (1) and (2) of Theorem 8.1 hold for all $v \in V^{K}$, then

$$
\begin{equation*}
\mathbb{Q} \cdot L\left(\mathfrak{X}_{\Gamma_{2}}\right)=\lambda \cdot \mathbb{Q} \cdot L\left(\mathfrak{X}_{\Gamma_{1}}\right) \quad \text { where } \quad \lambda=\sqrt{\frac{2 n+2}{2 n-1}} . \tag{30}
\end{equation*}
$$

We will show that provided the conditions (1) and (2) of Theorem8.1 hold, given a maximal $K$-torus $T_{1}$ of $\mathscr{G}_{1}$, there exists a maximal $K$-torus $T_{2}$ of $\widetilde{\mathscr{G}}_{2}$ and a $K$-isomorphism
$T_{1} \rightarrow T_{2}$ such that for any $\gamma_{1} \in T_{1}(K)$, and the corresponding $\gamma_{2} \in T_{2}(K)$, one can relate the following sets

$$
\left\{\alpha\left(\gamma_{1}\right) \mid \alpha \in \Phi\left(\mathscr{G}_{1}, T_{1}\right)\right\} \quad \text { and } \quad\left\{\alpha\left(\gamma_{2}\right) \mid \alpha \in \Phi\left(\widetilde{\mathscr{G}}_{2}, T_{2}\right)\right\},
$$

and derive information about the ratio of the lengths of the closed geodesics associated to $\gamma_{1}$ and $\gamma_{2}$. The easiest way to do this is to use the description of maximal $K$-tori of $\mathscr{G}_{1}$ and $\widetilde{\mathscr{G}}_{2}$ in terms of commutative étale algebras.

The group $\mathscr{G}_{1}$ can be realize as the special unitary group $\operatorname{SU}\left(A_{1}, \tau_{1}\right)$ where $A_{1}=$ $M_{2 n+1}(K)$ and $\tau_{1}$ is an involution of $A_{1}$ of orthogonal type (which means that $\operatorname{dim}_{K} A_{1}^{\tau_{1}}=$ $(2 n+1)(n+1)$ ). Any maximal $K$-torus $T_{1}$ of $\mathscr{G}_{1}$ corresponds to a maximal commutative étale $\tau_{1}$-invariant subalgebra $E_{1}$ of $A_{1}$ such that $\operatorname{dim}_{K} E_{1}^{\tau_{1}}=n+1$; more precisely, $T=\left(\mathrm{R}_{E_{1} / K}\left(\mathrm{GL}_{1}\right) \cap \mathscr{G}_{1}\right)^{\circ}$. It is more convenient for our purposes to think that $T_{1}$ corresponds to an embedding $\iota_{1}:\left(E_{1}, \sigma_{1}\right) \hookrightarrow\left(A_{1}, \tau_{1}\right)$ of algebras with involution, where $E_{1}$ is a commutative étale $K$-algebra of dimension $(2 n+1)$ equipped with an involution $\sigma_{1}$ such that $\operatorname{dim}_{K} E_{1}^{\sigma_{1}}=n+1$.

Similarly, the group $\widetilde{\mathscr{G}}_{2}$ can be realized as the special unitary group $\operatorname{SU}\left(A_{2}, \tau_{2}\right)$, where $A_{2}$ is a central simple algebra over $K$ of dimension $4 n^{2}$, and $\tau_{2}$ is an involution of $A_{2}$ of symplectic type (i.e., $\operatorname{dim}_{K} A_{2}^{\tau_{2}}=(2 n+-1) n$ ). Furthermore, any maximal $K$-torus $T_{2}$ corresponds to an embedding $\iota_{2}:\left(E_{2}, \sigma_{2}\right) \hookrightarrow\left(A_{2}, \tau_{2}\right)$ of algebras with involution where $E_{2}$ is a commutative étale $K$-algebra of dimension $2 n$ equipped with an involution $\sigma_{2}$ such that $\operatorname{dim}_{K} E_{2}^{\sigma_{2}}=n$.

Now, any involutory commutative étale algebra ( $E_{1}, \sigma_{1}$ ) as above admits a decomposition

$$
\left(E_{1}, \sigma_{1}\right)=\left(\widetilde{E}_{1}, \tilde{\sigma}_{1}\right) \oplus\left(K, \mathrm{id}_{K}\right)
$$

where $\widetilde{E}_{1} \subset E_{1}$ is a $(2 n)$-dimensional $\sigma_{1}$-invariant subalgebra and $\tilde{\sigma}_{1}=\sigma_{1} \mid \widetilde{E}_{1}$; note that $\operatorname{dim}_{K} \widetilde{E}_{1}^{\tilde{\sigma}_{1}}=n$. It was shown in [5] using Theorem 7.3 of [14] that if conditions (1) and (2) of Theorem 8.1 hold then $\left(E_{1}, \sigma_{1}\right)$ as above admits an embed$\operatorname{ding} \iota_{1}:\left(E_{1}, \sigma_{1}\right) \hookrightarrow\left(A_{1}, \tau_{1}\right)$ if and only if $\left(E_{2}, \sigma_{2}\right):=\left(\widetilde{E}_{1}, \tilde{\sigma}_{1}\right)$ admits an embedding $\iota_{2}:\left(E_{2}, \sigma_{2}\right) \hookrightarrow\left(A_{2}, \tau_{2}\right)$. This implies that for any maximal $K$-torus $T_{1}$ of $\mathscr{G}_{1}$ there exists a $K$-isomorphism $\varphi: T_{1} \rightarrow T_{2}$ onto a maximal $K$-torus $T_{2}$ of $\widetilde{\mathscr{G}}_{2}$ that is induced by the above correspondence between the associated algebras $\left(E_{1}, \sigma_{1}\right)$ and $\left(E_{2}, \sigma_{2}\right)$, and vice versa. Fix the tori $T_{1}, T_{2}$, the $K$-isomorphism $\varphi$, the algebras $\left(E_{1}, \sigma_{1}\right),\left(E_{2}, \sigma_{2}\right)$ and the embeddings $\iota_{1}, \iota_{2}$ for the remainder of this section. We also assume henceforth that the discrete torsion-free subgroups $\Gamma_{i} \subset \mathcal{G}_{i}$ are $\left(\mathscr{G}_{i}, K\right)$-arithmetic. Given $\gamma_{1} \in T_{1}(K) \cap \Gamma_{1}$, set $\gamma_{2}=\varphi\left(\gamma_{1}\right) \in T_{2}(K)$. Then there exists $n_{2} \geqslant 1$ such that $\gamma_{2}^{n_{2}} \in \Gamma_{2}$. It follows from the discussion at the beginning of $\$ 7$ that the ratio $\ell_{\Gamma_{2}}\left(c_{\gamma_{2} n_{2}}\right) / \ell_{\Gamma_{1}}\left(c_{\gamma_{1}}\right)$ of the lengths of the corresponding geodesics is a rational multiple of the ratio $\lambda_{\Gamma_{2}}\left(\gamma_{2}\right) / \lambda_{\Gamma_{1}}\left(\gamma_{1}\right)$. Let us show that in fact

$$
\begin{equation*}
\lambda_{\Gamma_{2}}\left(\gamma_{2}\right) / \lambda_{\Gamma_{1}}\left(\gamma_{1}\right)=\sqrt{\frac{2 n+2}{2 n-1}} . \tag{31}
\end{equation*}
$$

Indeed, let $x \in E_{1}$ such that $\iota_{1}(x)=\gamma_{1}$. The roots of the characteristic polynomial of $x$ are of the form

$$
\lambda_{1}, \ldots, \lambda_{n}, \lambda_{1}^{-1}, \ldots, \lambda_{n}^{-1}, 1
$$

for some complex numbers $\lambda_{1}, \ldots, \lambda_{n}$. Then

$$
\begin{equation*}
\left\{\alpha\left(\gamma_{1}\right) \mid \alpha \in \Phi\left(\mathscr{G}_{1}, T_{1}\right)\right\}=\left\{\lambda_{i}^{ \pm 1}\right\} \cup\left\{\lambda_{i}^{ \pm 1} \cdot \lambda_{j}^{ \pm 1} \mid i<j\right\} . \tag{32}
\end{equation*}
$$

For the corresponding "truncated" element $\tilde{x} \in \widetilde{E}_{1}=E_{2}$, the roots of the characteristic polynomial are

$$
\lambda_{1}, \ldots, \lambda_{n}, \lambda_{1}^{-1}, \ldots, \lambda_{n}^{-1}
$$

and

$$
\begin{equation*}
\left\{\alpha\left(\gamma_{2}\right) \mid \alpha \in \Phi\left(\mathscr{G}_{2}, T_{2}\right)\right\}=\left\{\lambda_{i}^{ \pm 2}\right\} \cup\left\{\lambda_{i}^{ \pm 1} \cdot \lambda_{j}^{ \pm 1} \mid i<j\right\} . \tag{33}
\end{equation*}
$$

Set $\mu_{i}=\log \left|\lambda_{i}\right|$. Then it follows from (32) that

$$
\lambda_{\Gamma_{1}}\left(\gamma_{1}\right)^{2}=\sum_{i=1}^{n}\left( \pm \mu_{i}\right)^{2}+\sum_{1 \leqslant i<j \leqslant n}\left( \pm \mu_{i} \pm \mu_{j}\right)^{2}=(4 n-2) \cdot \sum_{i=1}^{n} \mu_{i}^{2} .
$$

Similarly, we derive from (33) that

$$
\lambda_{\Gamma_{2}}\left(\gamma_{2}\right)^{2}=\sum_{i=1}^{n}\left( \pm 2 \mu_{i}\right)^{2}+\sum_{1 \leqslant i<j \leqslant n}\left( \pm \mu_{i} \pm \mu_{j}\right)^{2}=4(n+1) \cdot \sum_{i=1}^{n} \mu_{i}^{2} .
$$

Comparing these equations, we obtain (31). Then the inclusion $\supset$ in (30) follows immediately, and the opposite inclusion is established by a symmetric argument, completing the proof of Theorem 4.

Since the symmetric space of the real rank-one form of type $B_{n}$ is the (real) hyperbolic space $\mathbb{H}^{2 n}$, and the symmetric space of the real rank-one form of type $C_{n}$ is the quaternionic hyperbolic space $\mathbb{H}_{\mathbf{H}}^{n}$, we obtain the following.
Corollary 8.4. Let $M_{1}$ be an arithmetic quotient of $\mathbb{H}^{2 n}$, and $M_{2}$ be an arithmetic quotient of $\mathbb{H}_{\mathbf{H}}^{n}$ where $n \geqslant 3$. Then $M_{1}$ and $M_{2}$ satisfy $\left(T_{i}\right)$ and $\left(N_{i}\right)$ for at least one $i \in\{1,2\}$; in particular, $M_{1}$ and $M_{2}$ are not length-commensurable.
(We see from Theorem 1 that the same conclusion holds when $M_{1}$ is as in the above corollary but $M_{2}$ is an arithmetic quotient of $\mathbb{H}_{\mathbf{H}}^{m}$ with $m \neq n$.)

On the other hand, using Theorem 4, one can construct compact locally symmetric spaces with isometry groups of types $B_{n}$ and $C_{n}(n \geqslant 3)$, respectively, that are lengthsimilar - so, these spaces can be made length-commensurable by scaling the metric on one of them. According to the results of Sai-Kee Yeung [20], however, scaling will never make these spaces (or their finite-sheeted covers) isospectral.

## Appendix. Proofs of Theorems 5.7 and 5.7

First, we need to review some notions pertaining to the Tits index and recall some of the results established in [13]. Let $G$ be a semi-simple algebraic $K$-group. Pick a maximal $K$-torus $T_{0}$ of $G$ that contains a maximal $K$-split torus $S_{0}$ and choose coherent orderings on $X\left(T_{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ and $X\left(S_{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ (which means that the linear map between these vector spaces induced by the restriction $X\left(T_{0}\right) \rightarrow X\left(S_{0}\right)$ takes nonnegative elements to nonnegative elements). Let $\Delta_{0} \subset \Phi\left(G, T_{0}\right)$ denote the system of simple roots
corresponding to the chosen ordering on $X\left(T_{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$. Then a root $\alpha \in \Delta_{0}$ (or the corresponding vertex in the Dynkin diagram) is distinguished in the Tits index of $G / K$ if its restriction to $S_{0}$ is nontrivial. Let $\Delta_{0}^{(d)}$ be the set of distinguished roots in $\Delta_{0}$ and $P$ be the minimal parabolic $K$-subgroup containing $S_{0}$ determined by the above ordering on $\Phi\left(G, T_{0}\right)\left(\subset X\left(T_{0}\right)\right)$. Then $Z_{G}\left(S_{0}\right)$ is the unique Levi subgroup of $P$ containing $T_{0}$, and $\Delta_{0} \backslash \Delta_{0}^{(d)}$ is a basis of its root system with respect to $T_{0}$. Moreover, the set $\Phi\left(P, T_{0}\right)$ of roots of $P$ with respect to $T_{0}$ is the union of positive roots in $\Phi\left(G, T_{0}\right)$ (positive with respect to the ordering fixed above) and the roots $\Phi\left(Z_{G}\left(S_{0}\right), T_{0}\right)$ of the subgroup $Z_{G}\left(S_{0}\right)$; hence, $\Delta_{0} \backslash \Delta_{0}^{(d)}=\Delta_{0} \cap-\Phi\left(P, T_{0}\right)$. The set of roots of the unipotent radical of $P$ is the set of all positive roots except the roots which are nonnegative integral linear combination of the roots in $\Delta_{0} \backslash \Delta_{0}^{(d)}$.

The notion of a distinguished vertex is invariant in the following sense: choose another compatible orderings on $X\left(T_{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ and $X\left(S_{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$. Let $\Delta_{0}^{\prime} \subset \Phi\left(G, T_{0}\right)$ be the system of simple roots corresponding to this new ordering and $\Delta_{0}^{\prime(d)}$ be the set of distinguished simple roots. Then there exists a unique element $w$ in the Weyl group $W\left(G, T_{0}\right)$ such that $\Delta_{0}^{\prime}=w\left(\Delta_{0}\right)$ and we call the identification of $\Delta_{0}$ with $\Delta_{0}^{\prime}$ using $w$ the canonical identification. We assert that the canonical identification identifies distinguished roots with distinguished roots. To see this, note that if $P^{\prime}$ is the minimal parabolic $k$-subgroup containing $S_{0}$ determined by the new ordering, then there exists $n \in N_{G}\left(S_{0}\right)(K)$ such that $P^{\prime}=n P n^{-1}$. As $n T_{0} n^{-1} \subset Z_{G}\left(S_{0}\right)$, we can find $z \in Z_{G}\left(S_{0}\right)\left(K_{\text {sep }}\right)$ such that $z n T_{0}(z n)^{-1}=T_{0}$, i.e., $z n$ normalizes $T_{0}$, and $z n\left(\Delta_{0} \backslash \Delta_{0}^{(d)}=\Delta_{0}^{\prime} \backslash \Delta^{\prime(d)}\right.$. It is obvious that $z n P(z n)^{-1}=P^{\prime}$ and that $z n$ carries the set of roots which are positive with respect to the first ordering into the set of roots which are positive with respect to the second ordering. Therefore, $n z$ carries $\Delta_{0}$ into $\Delta_{0}^{\prime}$, and hence $w$ is its image in the Weyl group. From this we conclude that $w\left(\Delta_{0} \backslash \Delta_{0}^{(d)}\right)=\Delta_{0}^{\prime} \backslash \Delta_{0}^{\prime(d)}$, which implies that $w\left(\Delta_{0}^{(d)}=\Delta_{0}^{\prime(d)}\right.$. This proves our assertion.

We recall that $G$ is $K$-isotropic if and only if the Tits index of $G / K$ has a distinguished vertex, and, more generally, $\mathrm{rk}_{K} G$ equals the number of distinguished orbits in $\Delta_{0}$ under the $*$-action (for the definition and properties of the $*$-action see [13], §4).

Let now $T$ be an arbitrary maximal $K$-torus of $G$. Fix a system of simple roots $\Delta \subset \Phi(G, T)$. Let $\mathscr{K}$ be a field extension of $K$ such that both $T$ and $T_{0}$ split over it. Then there exists $g \in G(\mathscr{K})$ such that the inner automorphism $i_{g}: x \mapsto g x g^{-1}$ carries $T_{0}$ onto $T$ and $i_{g}^{*}(\Delta)=\Delta_{0}$. Moreover, such a $g$ is unique up to right multiplication by an element of $T_{0}(\mathscr{K})$, implying that the identification of $\Delta$ with $\Delta^{0}$ provided by $i_{g}^{*}$ does not depend on the choice of $g$, and we call it the canonical identification. A vertex $\alpha \in \Delta$ is said to correspond to a distinguished vertex in the Tits index of $G / K$ if the vertex $\alpha_{0} \in \Delta_{0}$ corresponding to $\alpha$ in the canonical identification is distinguished; the set of all such vertices in $\Delta$ will be denoted by $\Delta^{(d)}(K)$. Clearly, the group $G$ is quasi-split over $K$ if and only if $\Delta^{(d)}(K)=\Delta$. The notion of canonical identification can be extended in the obvious way to the situation where we are given two maximal $K$-tori $T_{1}, T_{2}$ of $G$ and the systems of simple roots $\Delta_{i} \in \Phi\left(G, T_{i}\right)$ for $i=1,2$; under the canonical identification $\Delta_{1}^{(d)}(K)$ is mapped onto $\Delta_{2}^{(d)}(K)$. The $*$-action of the absolute

Galois group $\operatorname{Gal}\left(K_{\text {sep }} / K\right)$ on $\Delta_{1}$ and $\Delta_{2}$ commutes with the canonical identification of $\Delta_{1}$ with $\Delta_{2}$, see Lemma 4.1(a) of [13]. The set $\Delta^{(d)}(K)$ is invariant under the $*$-action, so it makes sense to talk about distinguished orbits.

Let now $K$ be a number field. We say that an orbit of the $*$-action in $\Delta$ is distinguished everywhere if it is contained in $\Delta^{(d)}\left(K_{v}\right)$ for all $v \in V^{K}$. The following was established in [13], Proposition 7.2:

- An orbit of the $*$-action in $\Delta$ is distinguished (i.e., is contained in $\left.\Delta^{(d)}(K)\right)$ if and only if it is distinguished everywhere.
This implies the following (Corollary 7.4 in [13]):
- Let $G$ be an absolutely almost simple group of one of the following types: $B_{n}$ $(n \geqslant 2), C_{n}(n \geqslant 2), E_{7}, E_{8}, F_{4}$ or $G_{2}$. If $G$ is isotropic over $K_{v}$ for all real $v \in V_{\infty}^{K}$, then $G$ is isotropic over $K$. Additionally, if $G$ is as above, but not of type $E_{7}$, then $\mathrm{rk}_{K} G=\min _{v \in V^{K}} \mathrm{rk}_{K_{v}} G$.
Before proceeding to the proof of Theorem 5.7. we observe that since by assumption $L_{1}=L_{2}=: L$, it follows from condition (1) in the statement of that theorem that

$$
\theta_{T_{i}}\left(\operatorname{Gal}\left(L_{T_{i}} / L\right)\right)=W\left(G_{i}, T_{i}\right) \text { for } i=1,2
$$

So, the fact that there is a isogeny $T_{1} \rightarrow T_{2}$ defined over $L$ implies that $w_{1}=w_{2}$. Thus, this condition holds in both the Theorems 5.7 and 5.7. As we already mentioned, this implies that either the groups $G_{1}$ and $G_{2}$ are of the same Killing-Cartan type, or one of them is of type $B_{n}$ and the other is of type $C_{n}$ for some $n \geqslant 3$; in particular, the groups have the same absolute rank.

Proof of Theorem 5.7 for types $B_{n}, C_{n}, E_{8}, F_{4}$ and $G_{2}$. As we mentioned above, for these types we have

$$
\operatorname{rk}_{K} G_{i}=\min _{v \in V^{K}} \operatorname{rk}_{K_{v}} G_{i} \text { for } i=1,2 .
$$

Condition (2) of the theorem implies that $\mathrm{rk}_{K_{v}} G_{1}=\mathrm{rk}_{K_{v}} G_{2}$ for all $v \in \mathcal{V}$. On the other hand, for $v \notin \mathcal{V}$, both $G_{1}$ and $G_{2}$ are split over $K_{v}$, which automatically makes the local ranks equal. It follows that $\mathrm{rk}_{K} G_{1}=\mathrm{rk}_{K} G_{2}$. Furthermore, inspecting the tables in [18], one observes that the Tits index of an absolutely almost simple group $G$ of one of the above types over a local or global field $K$ is completely determined by its $K$-rank, and our assertion about the local and global Tits indices of $G_{1}$ and $G_{2}$ being isomorphic follows (in case $G_{1}$ and $G_{2}$ are of the same type).

Proof of Theorem 5.7 for types $B_{n}, C_{n}, E_{7}, E_{8}, F_{4}$ and $G_{2}$. It is enough to show that $G_{2}$ is $K_{2 v}$-isotropic for all $v \in V^{K_{2}}$, and in fact, since $G_{2}$ is assumed to be quasi-split over $K_{2 v}$ for all $v \notin \mathcal{V}_{2}$, it is enough to check this only for $v \in \mathcal{V}_{2}$. However by our construction, each $v \in \mathcal{V}_{2}$ is an extension of some $v_{0} \in \mathcal{V}_{1}$. Since $G_{1}$ is $K_{1}$-isotropic, we have

$$
\operatorname{rk}_{K_{2 v}} T_{1} \geqslant \operatorname{rk}_{K_{1 v_{0}}} T_{1}=\operatorname{rk}_{K_{1 v_{0}}} G_{1}>0,
$$

so the existence of a $K_{2}$-isogeny $T_{1} \rightarrow T_{2}$ implies that $\mathrm{rk}_{K_{2 v}} T_{2}>0$, hence $G_{2}$ is $K_{2 v}$-isotropic as required.

Thus, it remains to prove Theorems 5.7 and 5.7 assuming that $G_{1}$ and $G_{2}$ are of the same type which is one of the following: $A_{n}, D_{n}, E_{6}$ and $E_{7}$ (recall that Theorem 5.7 has already been proven for groups of type $E_{7}$ ). Then replacing the isogeny $\pi: T_{1} \rightarrow T_{2}$, which is defined over $K$ in Theorem 5.7 and over $K_{2}$ in Theorem 5.7, with a suitable multiple, we may (and we will) assume that $\pi^{*}\left(\Phi\left(G_{2}, T_{2}\right)\right)=\Phi\left(G_{1}, T_{1}\right)$. Besides, we may assume through the rest of the appendix that $G_{1}$ and $G_{2}$ are adjoint, and then $\pi$ extends to an isomorphism $\bar{\pi}: G_{1} \rightarrow G_{2}$ over a separable closure of the field of definition (cf. Lemma 4.3(2) and Remark 4.4 in [13). This has two consequences that we will need. First, the assumption that $L_{1}=L_{2}$ in Theorem 5.7 implies that the orbits of the *-action on a system of simple roots $\Delta_{1} \subset \Phi\left(G_{1}, T_{1}\right)$ correspond under $\pi^{*}$ to the orbits of the $*$-action on the system of simple roots $\Delta_{2} \subset \Phi\left(G_{2}, T_{2}\right)$ such that $\pi^{*}\left(\Delta_{2}\right)=\Delta_{1}$, and this remains true over any completion $K_{v}$. Thus, it is enough to prove for each $v \in V^{K}$ that $\alpha_{1} \in \Delta_{1}$ corresponds to a distinguished vertex in the Tits index of $G_{1} / K_{v}$ if and only if $\alpha_{2}:=\pi^{*-1}\left(\alpha_{1}\right) \in \Delta_{2}$ corresponds to a distinguished vertex in the Tits index of $G_{2} / K_{v}$. Similarly, the assumption that $L_{2} \subset K_{2} L_{1}$ in Theorem 5.7 implies (in the above notations) that if $O_{1} \subset \Delta_{1}$ is an orbit of the $*$-action, then $\left(\pi^{*}\right)^{-1}\left(O_{1}\right)$ is a union of orbits of the $*$-action. Consequently, it is enough to prove that if $\alpha_{1} \in \Delta$ corresponds to a distinguished vertex in the Tits index of $G_{1} / K_{1}$, then $\alpha_{2}:=\pi^{*-1}\left(\alpha_{1}\right) \in \Delta_{2}$ corresponds to a distinguished vertex in the Tits index of $G_{2} / K_{2 v}$ for all $v \in V^{K_{2}}$.

Second, given two systems of simple roots $\Delta_{1}^{\prime}, \Delta_{1}^{\prime \prime} \subset \Phi\left(G_{1}, T_{1}\right)$ and the corresponding systems of simple roots $\Delta_{2}^{\prime}, \Delta_{2}^{\prime \prime} \subset \Phi\left(G_{2}, T_{2}\right)$, an identification (induced by an automorphism of the root system) $\Delta_{1}^{\prime} \simeq \Delta_{1}^{\prime \prime}$ is canonical if and only if the corresponding identification $\Delta_{2}^{\prime} \simeq \Delta_{2}^{\prime \prime}$ is canonical.

Proof of Theorem 5.7 for the remaining types. As above, fix systems of simple roots $\Delta_{i} \subset \Phi\left(G_{i}, T_{i}\right)$ for $i=1,2$ so that $\pi^{*}\left(\Delta_{2}\right)=\Delta_{1}$. We need to show, for each $v \in V^{K}$, that a root $\alpha_{1} \in \Delta_{1}$ corresponds to a distinguished vertex in the Tits index of $G_{1} / K_{v}$ if and only if $\alpha_{2}:=\pi^{*-1}\left(\alpha_{1}\right) \in \Delta_{2}$ corresponds to a distinguished vertex in the Tits index of $G_{2} / K_{v}$. This is obvious if both $G_{1}$ and $G_{2}$ are quasi-split over $K_{v}$ as then all the vertices in the Tits indices of $G_{1} / K_{v}$ and $G_{2} / K_{v}$ are distinguished. So, it remains to consider the case where $v \in \mathcal{V}$. Let $S_{i}^{v}$ be the maximal $K_{v}$-split subtorus of $T_{i}$. Since $\mathrm{rk}_{K_{v}} T_{i}=\operatorname{rk}_{K_{v}} G_{i}$, we see that $S_{i}^{v}$ is actually a maximal $K_{v^{\prime}}$-split torus of $G_{i}$ for $i=1,2$, and besides, $\pi$ induces an isogeny between $S_{1}^{v}$ and $S_{2}^{v}$. Pick coherent orderings on $X\left(S_{1}^{v}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ and $X\left(T_{1}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ and on $X\left(S_{2}^{v}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ and $X\left(T_{2}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ that correspond to each other under $\pi^{*}$, and let $\Delta_{i}^{v} \subset \Phi\left(G_{i}, T_{i}\right)$ for $i=1,2$ be the system of simple roots that corresponds to this (new) ordering on $X\left(T_{i}\right) \otimes_{\mathbb{Z}} \mathbb{R}$; clearly, $\pi^{*}\left(\Delta_{2}^{v}\right)=\Delta_{1}^{v}$. Furthermore, let $\alpha_{i}^{v} \in \Delta_{i}^{v}$ be the root corresponding to $\alpha_{i}$ under the canonical identification $\Delta_{i} \simeq \Delta_{i}^{v}$; it follows from the above remarks that $\pi^{*}\left(\alpha_{2}^{v}\right)=\alpha_{1}^{v}$. On the other hand, $\alpha_{i}$ corresponds to a distinguished vertex in the Tits index of $G_{i} / K_{v}$ if and only if $\alpha_{i}^{v}$ restricts to $T_{i s}^{v}$ nontrivially, and the required fact follows.

Proof of Theorem 5.7 for the remaining types. Let $T_{1}^{0}$ be a maximal $K_{1}$-torus of $G_{1}$ that contains a maximal $K_{1}$-split torus $S_{1}^{0}$. As in the definition of the Tits index of $G_{1} / K_{1}$, we fix coherent ordering on $X\left(S_{1}^{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ and $X\left(T_{1}^{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$, and let $\Delta_{1}^{0}$ denote
the system of simple roots in $\Phi\left(G_{1}, T_{1}^{0}\right)$ corresponding to this ordering on $X\left(T_{1}^{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$. Now, pick $g_{1} \in G_{1}$ so that $T_{1}=i_{g_{1}}\left(T_{1}^{0}\right)$, and let

$$
\Delta_{1}=i_{g_{1}}^{*}\left(\Delta_{1}^{0}\right) \subset \Phi\left(G_{1}, T_{1}\right) .
$$

Furthermore, let $\Delta_{2} \subset \Phi\left(G_{2}, T_{2}\right)$ be the system of simple roots such that $\pi^{*}\left(\Delta_{2}\right)=\Delta_{1}$. It follows from the above discussion that it is enough to prove the following:
(*) Let $\alpha_{1}^{0} \in \Delta_{1}^{0}$ be distinguished in the Tits index of $G_{1} / K_{1}$, and let $\alpha_{1}=i_{g_{1}}^{*}\left(\alpha_{1}^{0}\right) \in$ $\Delta_{1}$. Then $\alpha_{2}:=\pi^{*-1}\left(\alpha_{1}\right) \in \Delta_{2}$ corresponds to a distinguished vertex of $G_{2} / K_{2 v}$ for all $v \in V^{K_{2}}$.

Since $G_{2}$ is quasi-split over $K_{2 v}$ for $v \notin \mathcal{V}_{2}$, it is enough to prove (*) assuming that $v \in \mathcal{V}_{2}$. By our construction, $v$ is an extension to $K_{2}$ of some $v_{0} \in \mathcal{V}_{1}$. Since $\operatorname{rk}_{K_{1 v_{0}}} T_{1}=$ $\mathrm{rk}_{K_{1 v_{0}}} G_{1}$, the maximal $K_{1 v_{0}}$-split subtorus $S_{1}^{v}$ of $T_{1}$ is a maximal $K_{1 v_{0}}$-split torus of $G_{1}$, so it follows from the conjugacy of maximal split tori (cf. 17, 15.2.6) that we can find an element $h_{1}$ of $G_{1}$, which is rational over a finite extension of $K_{1 v_{0}}$, such that

$$
T_{1}=i_{h_{1}}\left(T_{1}^{0}\right) \text { and } S_{1}^{v} \supset i_{h_{1}}\left(S_{1}^{0}\right)
$$

We claim that furthermore that to prove $(*)$ it suffices to find a different ordering on $X\left(T_{1}^{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ (depending on $v$ ) that induces the same ordering on $X\left(S_{1}^{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ (this ordering on $X\left(T_{1}^{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ will be referred to as the new ordering, while the ordering fixed earlier will be called the old ordering) such that if $\Delta_{1}^{0 v} \subset \Phi\left(G_{1}, T_{1}^{0}\right)$ is the system of simple root corresponding to the new ordering, $i^{*}: \Delta_{1}^{0} \simeq \Delta_{1}^{0 v}$ is the canonical identification, $\alpha_{1}^{0 v}=i^{*}\left(\alpha_{1}^{0}\right)$, and $\Delta_{1}^{v} \subset \Phi\left(G_{1}, T_{1}\right)$ and $\alpha_{1}^{v} \in \Delta_{1}^{v}$ are such that

$$
\begin{equation*}
i_{h_{1}}^{*}\left(\Delta_{1}^{v}\right)=\Delta_{1}^{0 v} \quad \text { and } \quad i_{h_{1}}^{*}\left(\alpha_{1}^{v}\right)=\alpha_{1}^{0 v} \tag{A.1}
\end{equation*}
$$

then for $\Delta_{2}^{v} \subset \Phi\left(G_{2}, T_{2}\right)$ such that $\pi^{*}\left(\Delta_{2}^{v}\right)=\Delta_{1}^{v}$, the root $\alpha_{2}^{v} \in \Delta_{2}^{v}$ such that $\pi^{*}\left(\alpha_{2}^{v}\right)=$ $\alpha_{1}^{v}$ corresponds to a distinguished vertex in the Tits index of $G_{2} / K_{2 v}$. Indeed, the identification $\Delta_{1} \simeq \Delta_{1}^{v}$ given by $i_{h_{1}}^{*} \circ i^{*} \circ\left(i_{g_{1}}^{*}\right)^{-1}$ is canonical and takes $\alpha_{1}$ to $\alpha_{1}^{v}$. It follows that the canonical identification of $\Delta_{2}$ with $\Delta_{2}^{v}$ takes $\alpha_{2}$ to $\alpha_{2}^{v}$, so the fact that $\alpha_{2}^{v}$ corresponds to a distinguished vertex in the Tits index of $G_{2} / K_{2 v}$ implies that the same is true for $\alpha_{2}$, as required. What is crucial for the rest of the argument is that due to the invariance of the Tits index, the root $\alpha_{1}^{0 v}$ is distinguished in the Tits index of $G_{1} / K_{1}$, i.e. its restriction to $S_{1}^{0}$ is nontrivial.

To construct a new ordering on $X\left(T_{1}^{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ with the required properties, we let $T_{2}^{0 v}$ denote a maximal $K_{2 v}$-torus of $G_{2}$ that contains a maximal $K_{2 v}$-split torus $S_{2}^{0 v}$. There exists $h_{2} \in G_{2}\left(K_{2 v}\right)$ such that

$$
\begin{equation*}
T_{2}=i_{h_{2}}\left(T_{2}^{0 v}\right) \text { and } S_{2}^{v} \subset i_{h_{2}}\left(S_{2}^{0 v}\right), \tag{A.2}
\end{equation*}
$$

where $S_{2}^{v}$ is the maximal $K_{2 v}$-subtorus of $T_{2}$. Since $\pi$ is defined over $K_{2}$, it follows from (A.1) and (A.2) that $\varphi:=i_{h_{2}}^{-1} \circ \pi \circ i_{h_{1}}$ has the property

$$
S_{1}^{0} \subset \varphi^{-1}\left(S_{2}^{0 v}\right)=: \mathcal{S}
$$

Lift the old ordering on $X\left(S_{1}^{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ first to a coherent ordering on $X(\mathcal{S}) \otimes_{\mathbb{Z}} \mathbb{R}$, and then lift the latter to a coherent ordering on $X\left(T^{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$. We claim that this ordering on $X\left(T^{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ can be taken for a new ordering. Indeed, as above, let $\Delta_{1}^{0 v} \subset \Phi\left(G_{1}, T_{1}^{0}\right)$ be the system of simple roots corresponding to the new ordering, and let $\alpha_{1}^{0 v} \in \Delta_{1}^{0 v}$
be the root corresponding to $\alpha_{1}^{0} \in \Delta_{1}^{0}$ under the canonical identification $\Delta_{1}^{0} \simeq \Delta_{1}^{0 v}$; as we already mentioned, $\alpha_{1}^{0 v}$ restricts to $S_{1}^{0}$ nontrivially. By construction, the system of simple roots $\Delta_{2}^{0 v} \subset \Phi\left(G_{2}, T_{2}^{0 v}\right)$ such that $\varphi^{*}\left(\Delta_{2}^{0 v}\right)=\Delta_{1}^{0 v}$ corresponds to a coherent choice of orderings on $X\left(S_{2}^{0 v}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ and $\alpha_{2}^{0 v} \in \Delta_{2}^{0 v}$ such that $\varphi^{*}\left(\alpha_{2}^{0 v}\right)=\alpha_{1}^{0 v}$ restricts to $S_{2}^{0 v}$ nontrivially, i.e. is a distinguished vertex in the Tits index of $G_{2} / K_{2 v}$. On the other hand, in the above notations we have

$$
i_{h_{1}}^{*}\left(\alpha_{1}^{v}\right)=\alpha_{1}^{0 v}, \quad \pi^{*}\left(\alpha_{2}^{v}\right)=\alpha_{1}^{v} \quad \text { and } \quad i_{h_{2}}^{*}\left(\alpha_{2}^{v}\right)=\alpha_{2}^{0 v}
$$

Thus, $\alpha_{2}^{v} \in \Delta_{2}^{v}$ corresponds to a distinguished vertex in the Tits index of $G_{2} / K_{2 v}$, as required.

[^0]:    ${ }^{1}$ We recall that a subset of a topological group was called solid in 13 if it meets every open subgroup of that group.

[^1]:    ${ }^{2}$ As we have seen in the proof of Theorem5.1 the former condition automatically implies the latter.
